The creep-fatigue damage due to a blowdown transient is independent of the rate of water-side blowdown following isolation. The damage depends primarily upon plant system characteristics which set the rate of IHTS sodium cooldown after reactor scram and main pump trip. The time delay between a small leak alarm and reactor scram should be considered as a tradeoff between (1) providing time to confirm the existence of the leak to a reasonable level of assurance and (2) the potential for secondary tube wastage damage. In general, there appears to be no incentive to delay water-side blowdown following scram because the additional stress damage due to blowdown is insignificant and the potential for wastage damage should be eliminated as quickly as possible. One exception is the case of multiple evaporators feeding a superheater (as for CRBRP) where isolation and blowdown of one evaporator shortly after scram can cause significant additional stress damage to the superheater upper tubesheet. When initiated, the water-side blowdown process should be rapid. About 30 seconds blowdown time appears practical and adequate, based on the CRBRP design. (ERA citation 06:034846)

Development of Depletion Perturbation Theory for a Reactor Nodal Code.
S. M. Bowman. Sep 81, 165p ORNL/TM-7589
Contract W-7405-ENG-26

A generalized depletion perturbation (DPT) theory formulation for light water reactor (LWR) depletion problems is developed and implemented into the three-dimensional LWR nodal code SIMULATE. This development applies the principles of the original derivation by M.L. Williams to the nodal equations solved by SIMULATE. The present formulation is first described in detail, and the nodal coupling methodology in SIMULATE is used to determine partial derivatives of the coupling coefficients. The modifications to the original code and the new DPT options available to the user are discussed. Finally, the accuracy and the applicability of the new DPT capability to LWR design analysis are examined for several LWR depletion test cases. The cases range from simple static cases to a realistic PWR model for an entire fuel cycle. Responses of interest included K/sub eff/, nodal peaking, and peak nodal exposure. The nonlinear behavior of responses with respect to perturbations of the various types of cross sections was also investigated. The time-dependence of the sensitivity coefficients for different responses was examined and compared. Comparison of DPT results for these examples to direct calculations reveals the limited applicability of depletion perturbation theory to LWR design calculations at the present. The reasons for these restrictions are discussed, and several methods which might improve the computational accuracy of DPT are proposed for future research. (ERA citation 06:034833)

The ORR operated at an average power level of 29.6 MW for 90.5% of the time during July, August, and September of 1980. The reactor was shut down on twelve occasions, five of which were unscheduled. Reactor downtime needed for refueling, maintenance, and checks was normal, with the reactor remaining available for operation 93.5% of the time. Maintenance activities, both mechanical and instrument, were essentially routine in nature. (ERA citation 06:034843)

The Nuclear Science Center is operated by the Texas Engineering Experiment Station as a service to Texas A and M University and the State of Texas. The facility is available to the University, other educational institutions, governmental agencies, and private organizations and individuals. Reactor utilization continued to grow during 1979 with an increase in the total number of irradiations, sample irradiation hours, number of samples irradiated, and total experiment hours. Reactor operation of 85.71 Mw-days for 1979 was essentially the same as the previous year. The reactor was not pulsed during the reporting period due to a restriction on pulsing until the fuel damage study is completed. (ERA citation 06:034842)

Intergranular stress corrosion cracking of welded type 304 stainless steel in the recirculation piping of boiling water reactors has had an impact on plant availability and reliability since the fall of 1974. Investigations of this problem have resulted in significant progress in understanding the phenomenon and providing an engineering resolution by developing and qualifying countermeasures. A number of these countermeasures including solution heat treatment, corrosion resistant clad, alternate pipe materials, induction heating stress improvement and heat sink welding have been implemented. Initial results from the experiment indicate that all significant events occurred as expected. In addition to conducting Test L6-5, preparations continued for the next small-break test, L3-7. Zircaloy is not compatible with oxide fuel nor with some fission product elements. Therefore, chemical interaction between the irradiated oxide fuel and the Zry cladding material take place, especially at temperatures that can be reached during reactor incidents (ATWS, LOCA). In order to find out which influence the chemical interaction between the fission products and the Zry cladding material have on the mechanical properties of Zry-4 tubing out-of-pile burst experiments and creep rupture tests have been performed at temperatures $>=600$ exp 0 C with short tube specimens containing simulated fission products. First of all, assessments of the chemical state of irradiated oxide fuel were performed and a method is described for introducing simulated fission product species into fresh oxide fuel for irradiation tests. As the test results of the out-of-pile studies show, only iodine can lead to a low ductility failure of the Zry-tubing at temperatures $>=600$ exp 0 C. However, the influence of iodine on the deformation behavior of Zry-tubing can be neglected above 850 exp 0 C. (Atomindex citation 10:473864)

The study describes the predicted response of Unit 1 at the Browns Ferry Nuclear Plant to Station Blackout, defined as a loss of offsite power combined with failure of all onsite emergency diesel-generators to start and load. Every effort has been made to employ the most realistic assumptions during the process of defining the sequence of events for this hypothetical accident. DC power is assumed to remain available from the unit batteries during the initial phase and the operator actions and corresponding events during this period are described using results provided by an analysis code developed specifically for this purpose. The Station Blackout is assumed to persist beyond the point of battery exhaustion and the events during this second phase of the accident in which DC power would be unavailable were determined through use of the MARCH code. Without DC power, cooling water could no longer be injected into the reactor vessel and the events of the second phase include core meltdown and subsequent containment failure. An estimate of the magnitude and timing of the concomitant release of the noble gas, cesium, and iodine-based fission products to the environment is provided in Volume 2 of this report.

Iron foil was used this quarter to help produce reducing conditions in a basic aqueous environment that resulted in only 0.02 ppB uranium in solution from the dissolution of sintered UO sub 2 , after one week's contact time. This concentration of uranium is the lower limit of detection in our analytical procedure. Additional work with powdered UO sub 2 to understand the conditions that result in low solubilities of uranium in aqueous solution has resulted in measured uranium concentrations of 8 ppB when hydrogen is used with palladium-black as the reducing agent. Calculations for this system show that CO sub 2 in solution is not affecting the results at pH 6 or lower. Electron microprobe analyses of a spent fuel segment have been completed. Plutonium concentrations were higher in the outer 500 mu m of the fuel element than in the interior. Strontium, antimony, and cesium did not display any radial trends in concentrations. Irradiated Fuel Inspection in a Storage Pond with No Fuel Movement and an Uncollimated Detector.
P. M. Rinard. Jul 80, 25p
Contract W-7405-ENG-36

It is assumed that the assemblies are not to be moved during the inspection in order to reduce the time required. The task is simplified further when the detector is well collimated. If the collimation is insufficient to respond to only one assembly from among an array of fuel assemblies, then an unfolding process is needed. A formulation of the detector's behavior is given followed by an unfolding process to yield the detector's response to each assembly as if it were isolated. Some simulated arrays are used to illustrate the sensitivity of the procedure to normal fluctuations in the measured quantities. Measurements with an ionization chamber on actual arrays of up to fourteen PWR assemblies are treated to provide a realistic application of the unfolding process. An unfolding technique is essential with a poorly collimated detector, but the examples warn that weak source strengths surrounded by much stronger sources will not be accurately recovered and even the detection of voids is thus uncertain. Some simulated arrays of up to 100 assemblies indicate that unacceptably inaccurate results may be caused by even the small normal fluctuations in measured values. Any use of an unfolding process is thus quite limited. (ERA citation 05:031668)

The interactive Pathfinding Simulation (PATHS) computer program treats the stochastic shortest route problem through the use of a Monte Carlo technique. This program is described in its application to the evaluation and design of facility security systems that are used for protection against sabotage and theft. By making use of an efficient algorithm for focusing upon only the relatively critical routes (from a security viewpoint), PATHS obviates the need to identify and evaluate each and every complete potential route. As a result, the PATHS procedure permits facility analyses that would otherwise be beyond the capabilities of current generation computers. Input requirements, input modifications, output options, and interpretation of the output are presented, and examples are given of simulations that apply to a hypothetical facility.

Weak-acid ion exchange resin is loaded with uranium by acid-deficient uranyl nitrate solutions that have a nitrate uranium ratio of about 1.6. Processing this solution from an acid-excess uranyl nitrate solution by thermal denitration in a screw denitrator is described. Direct processing of this solution resulted in an insufficient acid deficiency of about C/sub N//C/sub U/ = 1.8. Therefore, the process was modified; a highly denitrated UO sub 3 slid was processed with C/sub N//C/sub U/ = 0.2, and this solid was subsequently dissolved to prepare acid-deficient uranyl nitrate solution or slurry. A detailed flowsheet for this process is given. The proposed combined screw denitrator-dissolver unit may meet the process requiements with improved efficiency. (ERA citation 05:002576)

Rept no. ARBRL-TR-02370

Numerous previous tests demonstrated the effectiveness of polyethylene bars emplaced between rounds of M456 HEAT tank ammunition to prevent a second round detonation given the detonation of a first round. However, these tests had a considerable margin of safety and the reliability and associated confidence level were unknown. In this report, a description is given of the statistical design and tests which were performed to establish the shielding thickness needed to be 90% confident that the probability of a second round detonating, given a first round detonation, was less than 0.1. A number of observations in the literature indicate that the reactivity of side-chain substituents on tetrazoles (and other azoles as well) depends strikingly on whether the trivalent (pyrrole-type) nitrogen atom is located at the 1- or the 2- position of the tetrazole ring; this dependence has been observed in decarboxylation, hydrogen exchange, diazotization, nucleophilic substitution and other reactions. To understand these differences, physical measurements have been carried out on a number of tetrazole derivatives. 1H, 19F and 13C NMR studies, as well as dissociation constant measurements, have been carried out on a variety of isomeric pairs of tetrazole derivatives.

Final rept.,
J. L. Steger, C. J. Nietubicz, and K. R. Heavey. Oct 81, 82p Rept no. ARBRL-MR-03142

A planar grid generation routine has been developed for use with standard and non-conventional projectile shapes. Three-dimensional grid generation has been obtained by generating a sequence of planar grids about axis normal cross-sections. The method is basically automatic and generates smoothly varying grids for arbitrary body shapes and allows for grid point clustering. The program is modular and can be used to generate planar Cartesian-like grids, C-grids, O-grids, or any portion thereof. The routine can be used for axisymmetric projectiles with or without stings, symmetric tubular projectiles and for any configuration with an axisymmetric nose. Sample grids are presented along with the program listing and sample output. (Author)

Response of Containment Vessels to Explosive Blast Loading.
R. R. Karpp, T. A. Duffey, and T. R. Neal. Jun 80, 31p
Contract W-7405-ENG-36

The response of steel containment vessels to the blast loading produced by the detonation of high explosives is investigated by experiments, computations, and analysis. The vessels are thin-wall shell structures that are nearly spherical. All explosive charges are solid spheres, centrally initiated and centrally positioned within the vessels. Most of the work concerns vessels that contain, in addition to the explosive charge, air at ambient or reduced pressures. A scaling law that relates the first maximum strain occurring in the vessel wall to other relevant parameters is derived and shown to correlate the experimental data. One-dimensional, Lagrangian, finite-difference calculations are used to study the blast phenomenon and the details of the loading pulse applied to the vessel wall. The results are verified by comparisons with pressure gauge records. In addition, vessel response to the pressure loading is calculated by both finite-difference and finite-element computer codes. The two-dimensional motion, which occurs after significant wave interactions have taken place in the test vessels, can be simulated, with reasonable accuracy, by finite-element calculations. This result indicates that a predictive technique and, therefore, a design tool appear to be available with these standard calculational methods. The effects of a surrounding medium upon the peak strains occurring in a perfectly spherical vessel also are studied, and the reductions in strain caused by the inclusion of various surrounding media are estimated. Contract AC04-76DP00487

The purpose of this study was to develop a better understanding of the effects of machining properties upon tool forces encountered during lathe machining of high explosives, in order to optimize machining conditions for mechanical properties test specimens. Monetary considerations dictated that the tooling either already exist or be fabricated in-house using limited machine shop capability. The design chosen which fit between the tool holder and the tool post and interfaced to existing signal conditioners was easily fabricated. The study evaluated all forces on the cutter during machining of two types of high explosives at four cutter radii, four feed rates, three depths of cut and two cutting speeds. The study pointed out design problems, instrumentation drift, tool chatter and detection levels. It also showed that the type of high explosive was more significant than first thought toward influencing tool force levels. (ERA citation 05:027658)

Surface chemistry of Al/Cu sub 2 O thermite powders and pressed pellets undergoing accelerated aging was studied by x-ray photelectron spectroscopy (XPS) and Auger electron spectroscopy (AES). Al 1s, Cu 2P/sub 1/2/, Cu 2P/sub 3/2/, Cu L sub 3 -M sub 4 sub 5 M sub 4 sub 5 , O 1S, Al K-L sub 2 sub 3 , L sub 23 , C 1S, and Cu 3S signals were observed. The Al sub 2 O sub 3 film thicknesses on aluminum metal surfaces were deduced from signal intensity ratios of Al exp +3 and aluminum in XPS Al 2S as well as Al K-L sub 2 sub 3 L sub 2 sub 3 AES. The oxide thickness on the aluminum powder from the manufacturer was found to be 9A. Mixing of aluminum and Cu sub 2 O at room temperature to form thermite induced a certain degree of oxidation of the aluminum and increased the oxide film thickness to 11A. Hot pressing of thermite powders at 425 exp 0 C to from pellets increased the oxide layer to 22A. This oxide layer protected the aluminum fuel; further aging of these pellets at 180 exp 0 C for several months caused negligible change on the surface oxide. The bulk of the pellet was found to be stable and of good quality. (ERA citation 05:007562)

Independent Evaluation Plan for Crew Ballistic Shelter for the M110A2. Revision.

Revision of report dated Dec 79.

The results of Legal Mix V showed that the survivability of the M110 system could be significantly enhanced through the addition of ballistic protection to the M110 and its associated Ammunition Resupply Vehicle. The Crew Ballistic Shelter consists of a removable armored cab fastened to the vehicle turret. It is similar in shape and appearance to the present winterization kit. Sight openings and doors in the front and sides of the shelter provide for fire control sighting operations. An M8 NBC Collective Protection System is also included. The Ballistic Shelter will enhance the Field Artillery's support of maneuver forces by significantly improving survivability of the on-board crew against hostile artillery fire. The shelter will remain installed on the weapon for all normal operations, e.g., road march, firing, etc. The shelter can be removed by the organic howitzer crew with the aid of the organizational maintenance wrecker, when necessary, to facilitate maintenance or transportability. Both the howitzer and shelter can be transported on one flat car.

How to Make TIGER Perform: A Supplementary Operator's Manual for the TIGER Code.
Technical memo.,
Edward P. Petkus, and Kenneth J. Graham. Sep 81, 38p Rept no. NWC-TM-4650

TIGER is a digital computer code written in FORTRAN IV for calculating the thermodynamic state of a nonideal heterogeneous system of known composition. It was developed at Stanford Research Institute specifically for detonation calculations after experience with the RUBY code at Lawrence Livermore Laboratory and the BKW code at Los Alamos Scientific Laboratory had led to the conclusion that a more versatile code was required to perform routine and research calculations on condensed explosives. While RUBY is limited by its inability to treat certain explosive compositions, both RUBY and BKW are restricted by the inflexibility of their interlocking subroutines which, for example, prevent use of a new equation of state in a calculation without complete reprogramming. The TIGER code was constructed to avoid the problems associated with interdependent subroutines. The program was written in modular form so that the thermodynamics used to calculate the state, the hydrodynamics used to calculate detonation parameters, and the equations of state used to describe the properties of the system are treated separately in different parts of the code. Because of this separation, TIGER can be best described as a general code for calculating the thermodynamic properties of a nonideal heterogeneous mixture (described by an arbitrary equation of state), with the capability of calculating detonation parameters provided by the hydrodynamic option. It was conclusively demonstrated that aqueous foam can effect significant (greater than 10 dB) reductions in gun muzzle blast peak sound pressure level. Reductions of more than 10 dB were attained. In addition, muzzle flash was eliminated completely. Containment of the foam in a muzzle-mounted canister appears to offer a feasible and operationally acceptable method of exploiting the phenomenon. A fairly extensive comparison testing of blast transducers is presented. A number of blast transducers were exposed to a series of shock waves from the BRL 58 cm shock tube. Both the angle of shock incidence and the incident pressure levels were varied during the tests. The purpose of the study was to check the transducer's response and accuracy when misaligned to the flow direction. The complete sets of pressure-time records for representative transducer types are presented. The results show that, in general, none of the tested blast transducers measures the static or side-on pressures accurately independent of orientation. As a consequence, continual attention must be given to optimal transducer orientation and other considerations relevant to the blast transducer used.

An analytical model of the direct initiation of detonation waves with planar, cylindrical, and spherical symmetry is developed. This model shows that the energy requirements for the self-sustained detonation wave differ significantly for planar, cylindrical and spherical detonations. The new concept of minimum compensation energy was introduced and the technique of calculation of minimum initiation energy was developed. The results are verified by numerical simulation of the full governing equations and by comparison to experimental data. (Author)

This report describes a missile flight simulator research model developed to train DRAGON gunners. It is also being adapted to a variety of similar antiarmor weapons. The system employs a terrain board with enemy armored vehicles moving in a variety of attack scenarios. When the gunner fires the missile, hears computer generated rocket sounds and experiences the weight loss, recoil and smoke of the missile launch. When the smoke clears, he views the missile in the sight as well as the target. The gunner's aiming error is measured using a micro-processor-controlled diode matrix array. The matrix detector senses an IR emitting diode which is located on the miniature target. The flight equations of motion for the missile are solved by a 16 bit microprocessor every 0.02 seconds in each axis using gunner aiming error, target position, gravity, drag and side thruster accelerations as inputs. A second coordinated 16 bit processor controls a display that plots both vertical and horizontal aiming error for analysis of the gunner's performance by an instructor. Experienced DRAGON gunners have tested the system and attested to the realism and training potential. (Author)

The testing of Army weapon systems can be significantly improved through initial use of physical simulation testing. This report discusses two simulators that are available for testing weapons and weapon systems under conditions encountered during their life cycle. The one-degree-of-freedom (1-DOF) simulator provides a variable mounting platform from which weapons can be test fired to assess the effect of the mounting conditions on operability. Sections of vehicles to which weapons are mounted are suspended from the six-degree-of-freedom (6-DOF) simulator, which imparts various vibratory types of motions to the mounted vehicle and weapons fired under these realistic conditions. The report includes a discussion of the data acquisition system which provides immediate analysis of the data obtained from simulation testing. (Author)

The muzzle flash from cannon is analyzed using a simple description of the gun exhaust plume flow structure coupled to an empirical ignition criteria. The effect of muzzle devices such as recoil brakes is estimated through an approximate description of their internal flow. The influence of the transient nature of the weapon exhaust plume is examined by using a one-dimensional, unsteady numerical model to develop the flow properties along the axis of symmetry. These properties are input into the ignition model and the possibility of the occurrence of secondary combustion is determined as a function of time during gun tube emptying. (Author)

Numerical analysis is attempted on the gasdynamics associated with flow over an anti-recoil plate. The blast field is analyzed under the assumptions that the presence of the precursor flow and projectile may be neglected. An existing shock-fitting code is used in order to determine its capability when computing impingement flowfields. While the code provided good prediction of the exhaust flow from the muzzle of the gun up until shock impingement, problems were encountered in treating the flow following this event. It is clearly demonstrated that a major reshaping of the code has to be undertaken in order to provide efficient computational grids. (Author)

An experimental and theoretical study of the scattering of sound from the surface of a freshwater lake was performed. The study was limited to backscattered sound (reverberation) from a pulsed sound source. The experimental study employed nine vertically separated receivers and four horizontally separated receivers in order to examine the spatial and temporal covariance of the backscattered sound for both orientations simultaneously. Approximately 1000 narrowband reverberation returns were generated by repetitively projecting a 100 microsec CW pulse centered at 80kHz at the wind-roughened surface of a freshwater lake at a 10.5 degree grazing angle. The returns were sampled digitally for a 10 msec interval during which surface reverberation was predominant, and were formed into ensembles at each sample time. Significant differences were observed between the covariances of the vertical and horizontal arrays. The envelope of the covariance between the vertical receivers maintained a significant level at much larger separations than the horizontal receivers. The phase of the vertical covariance was found to change linearily with time, resulting in a slow oscillation of the covariance with time, while the phase of the horizontal covariance was constant (and non-zero). The vertical covariance was also shown to depend on the location of the elements on the array.

Significant progress has been made toward developing large-diameter, semi-insulating GaAs crystals of improved quality by LEC growth for direct ion implantation. The intent has been to (1) develop a reproducible twin-free growth technique for large-diameter 50-mm and 75-mm GaAs crystals; (2) achieve stable, semi-insulating substrate properties without resorting to intentional doping with chromium (or at least to reduce the Cr content significantly) to avoid the serious redistribution problems associated with this impurity; (3) obtain uniform, predictable doping characteristics by direct 29Si implantation; and (4) demonstrate that uniform, round cross-section slices suitable for low-cost IC processing can be fabricated from LEC crystals.

The role played by sources and sinks of point defects is of importance in understanding a wide range of physical phenomena. The problem of the efficiency (eta) of a sink (or sources) and its relationship to the super (or sub) saturation of point defects which drives the process is considered. A qualitative discussion is given of the atomic mechanisms by which the following defects act as sources and sinks: (a) the free surface; (b) voids; (c) dislocation loops; and (d) grain boundaries. Examples of specific values of eta are given for

different experimental situations. (ERA citation 06:035663)

Growth of Solid Solution Single Crystals.
Final Report.
A. F. Witt. Oct 81, 12p NASA-CR-161891
Contract NAS8-32994

The bulk growth of HgCdTe crystals by modified Bridgman techniques and by quenching anneal recrystallization yields deficient material. The primary complication for growth arises from a pronounced tendency for constitutional supercooling caused by the characteristics of the phase diagram and from the high vapor pressure of Hg. Unseeded and seeded Bridgman growth are considered from the viewpoints of: (1) backmelting of a solid charge; (2) equilibration prior to regrowth; and (3) the growth process. A growth system developed to restrict the thermal gradient region in the melt is described which is based on differentially operated heat pipes (isothermal regions) separated by an (adiabatic) gradient region, this permits maximized radial thermal gradient control, which is desirable for the establishment of a planar solidification isotherm.

Comparison of Profile and Integrated-Intensity Methods in Powder Refinement.
Final rept.,
E. Prince. 1981, 3p
Pub. in Jnl. of Applied Crystallography 14, p157-159 1981.

If a powder pattern consists of well resolved peaks, and if it is adequately described by a crystallographic model, as determined by statistical tests, the estimates of the parameters and their standard deviations will not be significantly different, in a statistical sense, whether the method of refinement uses peak profiles or integrated intensities. If the model does not fit adequately, the standard deviations cannot be calculated by statistical methods. If peaks overlap, there are correlations between the intensities of the individual peaks that are handled automatically in the profile method, but must be included explicitly in the integrated-intensity method. A background function should be included in the model, and its parameters refined. The background parameters have correlations with other parameters that become important if the pattern is complex, and therefore poorly resolved.

The fundamentals of ion motion in electromagnetic fields are reviewed in detail with a special emphasis on electric radiofrequency (RF) fields which are used frequently in dynamic mass spectrometry. Forces and effects on ions in electromagnetic fields which are typically neglected, but which may be important in practical applications, are reviewed and discussed for completeness. A method based on complex variable theory is developed for finding the potential function of 'ideal multiplole electromagnetic fields.' Application of this method for the determination of potential functions and differential equations of ion motion is demonstrated with reference to the electric radiofrequeny dipole, quadrupole, hexapole, octapole, and decapole fields. The results and implications of this preliminary communication and tutorial are of importance in ion physics and dynamic mass spectrometry. (Author)

The basic principles of a device for catching and dissipating the kinetic energy of a jet are described and a design of a particular form of the jet catcher outlined. This has been in use for some time as part of the RAE Boundary Layer Tunnel and has proved completely successful in eliminating unwanted air currents in the test room of the tunnel. The device should have wide applications in industry in general and in aeronautics in particular in situations where high energy jets may be a source of nuisance or even of danger. High Solitary Waves in Water: Results of Calculations,
James M. Witting. 30 Sep 81, 20p Rept no. NRL-8505

This report presents results of calculations of certain properties of solitary waves in water as a function of wave strength, with emphasis on the highest and other high waves. A preceding report outlines the method used to arrive at the results presented here. The method involves a Fourier series solution of the flow field at various (numerical) resolutions to arrive at an estimate of limits as the resolution becomes infinitesimal. Values of the properties of intermediate and high waves possess 4 to 6 significant figure accuracies. For some solitary wave parameters, the calculations agree well with those found using independent methods and verify that the total energy and other integral properties reach a maximum at strengths less than that of the highest wave. They also verify that the maximum angle of surface inclination can exceed 30 deg. for the not-quite-highest waves. In addition, this report gives solitary wave properties useful in constructing periodic wave solutions by the superimposition of solitary waves. The highest wave in water is higher than previously reported; its amplitude to depth ratio is 0.8332. (Author)

Diffusion of Gases in Capillaries.
N. S. Jacobson. Aug 81, 108p LBL-13227
Contract W-7405-ENG-48
Thesis.

Two aspects of the diffusion of gases in capillaries are explored. In Part I a Monte Carlo computer simulation of Knudsen flow is adapted to count collisions and record collision distributions. Using this simulation, the behavior of gases in both open and closed end tubes is examined. Given a tube with one end closed and a length-to-radius ratio of L/R, it is shown that a molecule that enters this tube will strike the wall an average of 2 L/R times before escaping. It is also shown that most molecules do not travel very far into the pore. However, those that reach the pore bottom usually strike the walls many times before escaping. The average number of collisions a molecule undergoes in passing through an open-end capillary is also calculated. If the reaction probability is already known, the processes in a supported catalyst can be simulated. From this analysis the distribution of active material, pore size, and pellet diameter can be optimized for a given reaction. Part II is an experimental study of Knudsen and surface diffusion in porous alumina. This material had pores 1.1 to 1.3 mu in diameter and was used as barriers 1.124 to .114 mm thick. It is shown that He, Ar, N sub 2 , O sub 2 , CO sub 2 , CH sub 4 , NH sub 3 , and SO sub 2 all pass through these barriers by Knudsen diffusion at room temperature. At 631 exp 0 K, zinc vapor also passes through this material by Knudsen flow. However, NaCl, NaF, and LiF vapors show substantial elements of surface diffusion with surface flux to Knudsen flux ratios of 1.6, 5.1, and 11.2, respectively. (ERA citation 06:035581)

CONCHAS: An Arbitary Lagrangian-Eulerian Computer Code for Multicomponent Chemically Reactive Fluid Flow at All Speeds.
T. D. Butler, L. D. Cloutman, J. K. Dukowicz, and J. D. Ramshaw. Nov 79, 197p
Contract W-7405-ENG-36

The CONCHAS computer code, which solves the equations of transient multicomponent chemically reactive fluid dynamics in two space dimensions is de-

scribed. CONCHAS is a time-marching finite-difference code that utilizes a partially implicit numerical scheme and a generalized mesh. Both planar and axisymmetric problems may be solved. Spatial differences are formed with respect to a two-dimensional mesh whose cells are arbitrary quadriaterals. The location of the cell corners, or vertices, may be arbitrarily specified as functions of time, thereby allowing a Lagrangian, Eulerian, or mixed description. This capability is particularly useful for representing curved and or moving boundary surfaces. Arbitrary numbers of species and chemical reactions are allowed. Discussions are given of the governing equations, the numerical scheme, and the code structure. A FORTRAN listing of the code is also provided. (ERA citation 05:012308)

A Wake Source Model for Asymmetric Potential Flow past Bodies of Wedge Shape.
P. A. T. Christopher, and I. Wolton. Oct 81, 55p C-OF-A-MEMO-8112

The wake source model of Parkinson & Jandali was generalized in several ways to accommodate the lack of symmetry and the experimentally observed difference in base pressure at the points of flow separation. A basic indeterminacy is revealed which arises partly from the simple form of the model and partly from the Schwarz-Christoffel mapping employed. This indeterminacy is shown to be relatively unimportant in one symmetric case, but leaves open the more general case to further exploration. Application of the method to wedges having short and long afterbodies shows that, in the former case, the agreement between theory and experiment is substantially better than that for the long afterbody.

P. A. T. Christopher, and C. T. Shaw. Oct 81, 52p C-OF-A-MEMO-8110

A method is presented for determining the potential flow around bodies of revolution, at incidence, in uniform, incompressible, flow. This method utilizes polynomial distributions of both sources and doublets, and give considerable advantage over existing techniques. In particular, in a typical case, the computer storage requirement is reduced by a factor of eleven. Compared with panel methods the saving is very much greater. Both body surface and flow field conditions are obtainable and it would appear that the new method is ideally suited to the store trajectory application in place of the existing discrete source method.

Presented at the 5TH Aiaa Computational Fluid Dyn. Conf., Palo Alto, Calif., 22-23 Jun. 1981.

A general, user oriented computer program, called VNAP2, was developed to calculate high Reynolds number, internal/ external flows. The VNAP2 program solves the two dimensional, time dependent Navier-Stokes equations. The turbulence is modeled with either a mixing-length, a one transport equation, or a two transport equation model. Interior grid points are computed using the explicit MacCormack Scheme with special procedures to speed up the calculation in the fine grid. All boundary conditions are calculated using a reference plane characteristic scheme with the viscous terms treated as source terms. Several internal, external, and internal/external flow calculations are presented.

A. B. Cain, W. C. Reynolds, and J. H. Ferziger. Aug 81, 140p NASA-CR-164942, SU-TF-14
Contract NCC2-15

The physics of the transition and early turbulence regimes in the time developing mixing layer was investigated. The sensitivity of the mixing layer to the disturbance field of the initial condition is considered. The growth of the momentum thickness, the mean velocity profile, the turbulence kinetic energy, the Reynolds stresses, the anistropy tensor, and particle track pictures of computations are all examined in an effort to better understand the physics of these regimes. The amplitude, spectrum shape, and random phases of the initial disturbance field were varied. A scheme of generating discrete orthogonal function expansions on some nonuniform grids was developed. All cases address the early or near field of the mixing layer. The most significant result shows that the secondary instability of the mixing layer is produced by spanwise variations in the straining field of the primary vortex structures.

In order to calculate the velocity and scalar fields, the three dimensional, time-dependent equations of motion and the diffusion equation were solved numerically. The following cases were treated: isotropic, homogeneous turbulence with decay of a passive scalar; and homogeneous turbulent shear flow with a passive scalar whose mean varies linearly in the spanwise direction. The solutions were obtained at relatively low Reynolds numbers so that all of the turbulent scales could be resolved without modeling. Turbulent statistics such as integral length scales, Taylor microscales, Kolmogorov length scale, one- and two-point correlations of velocity-velocity and velocity-scalar, turbulent Prandtl/Schmidt number, r.m.s. values of velocities, the scalar quantity and pressure, skewness, decay rates, and decay exponents were calculated. The results are compared with the available expermental results, and good agreement is obtained.

The fundamentals of large eddy simulation are considered and the approaches to it are compared. Subgrid scale models and the development of models for the Reynolds-averaged equations are discussed as well as the use of full simulation in testing these models. Numerical methods used in simulating large eddies, the simulation of homogeneous flows, and results from full and large scale eddy simulations of such flows are examined. Free shear flows are considered with emphasis on the mixing layer and wake simulation. Wall-bounded flow (channel flow) and recent work on the boundary layer are also discussed. Applications of large eddy simulation and full simulation in meteorological and environmental contexts are included along with a look at the direction in which work is proceeding and what can be expected from higher-level simulation in the future.

A direct, low Reynolds number, numerical simulation was performed on a homogeneous turbulent shear flow. The full compressible Navier-Stokes equations were used in a simulation on the ILLIAC IV computer with a 64,000 mesh. The flow fields generated by the code are used as an experimental data base, to examine the behavior of the Reynols stresses in this simple, compressible flow. The variation of the structure of the stresses and their dynamic equations as the character of the flow changed is emphasized. The structure of the tress tensor is more heavily dependent on the shear number and less on the fluctuating Mach number. The pressure-strain correlation tensor in the dynamic uations is directly calculated in this simulation. These correlations are decomposed into several parts, as contrasted with the traditional incompressible decomposition into two parts. The performance of existing models for the conventional terms is examined, and a model is proposed for the 'mean fluctuating' part.

During this period we investigated the production of excited metal atoms by the photodissociation of volatile metal--encapsulated compounds. Specifically, we studied FE(CO)5, Fe(CO)3, CH2CHCHCH2, 1,1'dimethyl, ferrocene, Ni(CO)4, Zn(CH3)2, Mn(CO)5Cl and Mn(CO)6. In all cases atomic emission is observed when a few torr of the parent compound is irradiated by the 2458 angstroms output of a KrF laser (15mJ/pulse). Most of this grant period was devoted to the fabrication of the KrF laser. This device is presently operational and plans are underway to modify it so that it will also operate as a ArF laser (1930 angstroms output).

Fluorescent Glasses for Use in Fluorescently Pumping Nd 3(+) Doped Laser Glass.
Special rept.,
C. F. Rapp. Aug 81, 12p
Contract N00014-81-C-2376

In certain cases it may be desirable to fluorescently pump a neodymium doped laser glass rather than directly excite the laser glass with the light from a flashlamp. That is, the flashlamp energy is first absorbed in a fluorescent material which then reemits to fluorescently pump the Nd3+ laser glass. This fluorescent pumping could be beneficial in two ways; first, the short wavelength radiation which is not efficiently absorbed by the neodymium can be converted to wavelengths which are strongly absorbed; and, second, the conversion of short wavelength pump light to longer wavelengths will minimize the amount of heat generated in the laser rod. However, if the fluorescent material is to efficiently pump the neodymium, and not simply absorb and waste the short wavelength radiation from the flashlamp, it must display several characteristics.

Contracts AC04-77AL03914, AC04-78AL14199

The investigation of laser isotope separation (LIS) of uranium starting with UF sub 6 feed stock has required the development of new infrared lasers. Certain R branch lines of the 16 mu m bending mode transition, 02 exp 0 0 implies 01 exp 1 0, in CO sub 2 fall within one of the infrared wavelength regions of interest for this application. This report presents the results of experimental and theoretical studies of the operational characteristics of this 16 mu m CO sub 2 bending mode laser. The initial phase of the research program was devoted to a study of the feasibility of using simple pulsed electrical discharges as an excitation source for this laser system. The activities conducted under this phase of the program included: experimental studies of 16 mu m laser emission; development of a computer model to explain the observed experimental results and to predict behavior under other operating conditions; and development of a preliminary conceptual design for a deliverable laser system. The following optical properties of both single-crystal and press-forged LiF were evaluated in the program: optical homogeneity at 633 nm, stress birefringence, scattering at 633 nm, residual absorption over the spectral range 339 to 3800 nm, and laser damage thresholds for 1-ns, 1064-nm and 700-ps, 266-nm laser pulses. The results of the optical characterization tasks indicate that LiF single crystals can be press-forged without seriously degrading their optical properties. The following mechanical properties of both single-crystal and press-forged LiF were evaluated: yield strength in compression, proportional limit and fracture strength in 3- and 4-point bending, fracture energy, and threshold for microyield. The results indicate that the mechanical properties of LiF single crystals can be improved significantly by press forging. (ERA citation 05:033121)

Materials studies as well as general and specific device development were carried out in the InGaAsP system. A comparison was made of three standard methods of evaluating substrate quality by means of dislocation studies. A cause of reduced yield of good wafers, the pullover of melt from one bin to the next, has been analyzed. Difficulties with reproducible zinc acceptor doping have been traced to segregation of zinc in the In/Zn alloy used for the doping source. Using EBIC measurments, the pn junction was shown to drift in location depending on factors not always under control. An analysis of contact structures by SIMS showed that the depth to which the sintered Au/Zn contact penetrates into the structure is typically 0.13 microns, or well within the cap layer and out of the p-type cladding and thus not deleterious to laser prformance. The problem of single-mode laser development was investigated and it was shown to be related to the growth habit over four different possible substrate configurations. The fabrication of constricted double heterojunctions, mesa stripe buried heterostructures, and buried heterostructures was discussed, and measurements were presented on the device properties of single-mode buried heterostructure lasers. Results include single spectral line emission at 3 mW and a threshold current of 60 mA.

Structural Design of a Large Deformable Primary Mirror for a Space Telescope.
Doctoral thesis,
James Gerald Raymond Hansen. 1981, 187p Rept no. AFIT-CI-81-15D

A 4 meter aperture deformable primary mirror is designed with the mirror and its supports integrated into a single structure. The integrated active mirror's minimal weight makes it desirable for a space telescope as well as a terrestrial application. Utilizing displacement actuators, the active controls at the mirror's surface include position control and slope control in both the radial and tangential directions at each of the 40 control points. Influence functions for each of the controls are nearly independent, reducing the complexity of the control system. Experiments with breadboard models verify the structural concept and the techniques used in the finite element method of computer structural analysis. The majority of this paper is a description of finite element analysis results. Localization of influence functions is exhaustively treated. For gravity loads, a thermal gradient through the mirror thickness, and a uniform thermal soak, diffraction limited performance of the 4m design is evaluated. Loads are applied to defocus the mirror and to cause fourth-order astigmatism. Mirror scallop, instigated by a focus shift, has been virtually eliminated with the 40-actuator design. The structural concept is so effective that it should be considered for uncontrolled primary mirrors as well as active mirrors.

Annual summary rept. 1 Jul 80-30 Jun 81,

Contract N00014-80-C-0941

The series combination of a semiconductor-diode gain element (a diode laser whose end facets have been antireflection coated) and an optical fiber has been placed inside an external cavity and the external cavity has lased in a single spectral line whose width was less than the 1.7 x 10 to the -5-nm resolution of the scanning Fabry-Perot interferometer used. When a grating in the Littrow configuration is used as one of the cavity end reflectors the spectral line can be tuned. Other elements such as a polarizer can also be placed inside the cavity to select a desired mode of operation. The addition of elements inside the external cavity (including the optical fiber) introduces loss which increases both the threshold current for laser operation and the ratio of power at the gain element facet to cavity output power. With optimized design the long mean life of the semiconductor laser can be maintained by reducing the output power per gain element by less than 33 percent. In terms of the overall goal of this program, The Fiber-Coupled External Cavity Semiconductor Laser, the results obtained are extremely encouraging. (Author)

We performed a theoretical and experimental study of a 10.6 micrometer heterodyne detection system with nonlinear postdetection. A single laser acts as both transmitter and local oscillator; the intermediate frequency is given by Doppler effect due to a rotating target. An electrooptic crystal amplitude-modulates the laser beam at a frequency of 15 kHz; a synchronous voltmeter measures this signal after the nonlinear element. Values of signal-to-noise ratio with respect to incident optical power are in agreement with the results of the theoretical model. In particular, experimentally measured target-induced frequency spreading effects on signal-to-noise ratio correspond to the predictions of the model.

Contract DAAG29-78-C-0028

The dynamics and wavelength dependence of recording and optical erasure of thick phase gratings produced photorefractively were studied in undoped and in iron-doped lithium niobate. Properties of gratings formed at high incident power densities via two-photon absorption were compared with those of gratings formed at shorter wavelengths by the usual one-photon mechanism. Gratings formed by the two-photon mechanism in undoped crystals exhibit a distinctive two-exponential time dependence of optical erasure not observed in other circumstances. This shows that the nature of final trap states, as well as absorption and charge transfer characteristics, is important in controlling photorefractive sensitivity. A method was discovered for producing high diffraction efficiency gratings at infrared frequencies in titanium-diffused optical waveguides on lithium niobate. (Author)

The surface finish of a single-point diamond-turned (SPDT) mirror produced in 1977 on the large (2-meter swing) Excello lathe at the Union Carbide Corporation's Y-12 Plant in Oak Ridge, Tennessee, was such that it was not possible to do visible alignment using it. Therefore, it was necessary to polish the mirror by hand. This was done at the University of Arizona. The intent was to remove the high ridges in the SPDT mirror but not to degrade the figure. Both interferometric and encircled energy measurements were made on the mirror before and after polishing. The mirror was an f/2 off-axis parabola 39.37 cm in diameter. The equation describing the generator of the mother parabola is y exp 2 = 309x(cm exp 2) and the center of each off-axis sister mirror is at x = 7.64 cm, and y = 48.59 cm. After polishing it was possible to align it using techniques which employed visible light. (ERA citation 04:055852)

A schlieren system of the z-type configuration is described which measures the chromatic dispersion of gradient refractive index optical glass samples. Components of the system, i.e., lenses, are composed of materials whose index of refraction varies in a prescribed manner. The chromatic dispersion is assessed by measuring the maximum slope of the gradient profile represented mathematically as a polynomial, as a function of wavelength. The schlieren instrument assesses the maximum slope by measuring light deflected by the samples. Angular deflections of light from 5-40 milliradians are typical for the samples measured. Eight gradient samples are measured by the schlieren system and the measurements compared to their documentation by a.c. interferometry. The accuracy is one and one-half to five times (dependent on gradient strength) that of a.c. interferometry. Also, the schlieren system has other distinct advantages in measuring maximum slopes when compared to a.c. interferometry. Suggestions for improvements and future investigations are presented. An appendix details the operating procedure of the schlieren system.

The design, evaluation, and performance of a system for determining the magnitude of the transfer function(hence, bandwidth) of a multimode optical fiber are presented. The system operates to about 1450 MHz using a tracking generator/spectrum analyzer combination for narrowband detection. It is constructed, almost entirely, from commercially available components. The system is less complex and easier to use than an equivalent time domain system and the measurement precision is comparable. Background information on time and frequency domain specifications, fiber bandwidth limitations, and alternate frequency domain techniques is also presented.

By exploiting recent developments in plasma physics a program to diagnose changes in source properties during ion beam extraction has been initiated to improve source efficiency. A small cyclotron with a conventional hooded arc provides radiation from excited species (H/sub beta / and the 4685 A line of HeII) which is spectrally analyzed and detected by a high-frequency photomultiplier. The intensity of the radiation is sensitive to changes in the electron and ion densities, and enables an analysis of the effect of the rf field on the plasma properties of the source. We have evidence that coupling of the rf extraction field to normal modes of the plasma - the Electrostatic Ion Cyclotron waves - occurs, permitting rf field penetration to the entire plasma column and large beam extraction. The operation of the Dubna synchrophasotron in the 2nd quarter of 1978 when accelerating deuterons, C, O and Ne nuclei is presented. The KRION electron-beam source with improved characteristics has been used as a source of nuclei. This permits a marked increase of the nuclei intensity to be obtained at its output. The carbon, oxygen and neon nuclei are accelerated. The CKM-200 streamer chamber has been first exposed to an extracted beam of Ne nuclei with an energy of 4.1 GeV/nucleon. In order to get information on the accelerated beams of low intensity nuclei, new transmitters of two types are used. To improve the characteristics of the operating magnetic field, the work has been in progress during the synchrophasotron shutdown. A new system of geodetic measurements is used for more effective control of the position of the synchrophasotron electromagnet. Data on vertical motions of the electromagnet, obtained in two runs, are presented. (Atomindex citation 10:473734)

Presented are the results of studying the operation of distributive cathodes of a direct and indirect incandescence in duoplasmatron ion sources. The KP-25V direct-incandescent distributive cathode is a spiral of a porous tungsten impregnated with barium-calcium alumosilicate. It is shown that the KP-25V cathode provides emission current density up to 5 A/cm exp 2 in a continuous regime. Direct-incandescent distributive cathodes have certain advantages as compared to those of an indirect incandescence, i.e. they have a large emission surface and high reliability. Cathodes of the both types quickly recover their emission properties after being kept in air. Dependences of beam current and composition of ion beam drawn out of the NG-50 neutron generator duoplasmatron are presented to illustrate emission properties of ion source. Ion beam current up to 15 mA is provided at the content of atomic component up to 80%, the HG-50 operating with the diameter of emission hole of O.3 mm and discharge current of 3 A at the 0.2 mm diameter provided is ion beam current up to 5 mA. The US and USSR's most recent evaluationsof exp 235 U, exp 239 Pu, exp 240 Pu and exp 241 Pu are compared over the thermal region and over the first few resonances. The two evaluations rest on essentially the same experimental data base and the differences reflect different approaches to the representation of the cross sections or different weightings of the experimental results. It is found that over the thermal and resolved ranges the two evaluations are very similar. Some differences in approaches are briefly discussed. (ERA citation 06:035646)

Multiplicity, energy and angular distributions of protons of energies over 20MeV emitted in pion-xenon nuclei collisions at 3.5GeV/c are presented in reactions not accompanied by the multiparticle production.It is shown that the energy spectra of fast protons emitted forward and those emitted in backward direction are lying in the kinetic energy intervals 20-250 MeV. The ratio of the number of protons emitted in the forward direction to the number of those in backward direction equals 1.78+-0.11 in the sample of all 318 events, and 1.69+-0.20 in events with zero secondary pions. Asymmetry is shown in the azimuth angle distribution of protons; inmonotony of proton multiplicity distribution is seen. (Atomindex citation 10:493455)

Deep inelastic scattering of charged leptons on nuclei is considered in the lowest order in electromagnetic interaction. Expressions for the corresponding differential cross sections are obtained provided the scattered lepton and the fragment of the initial nucleus are detected in coincidence. Structure functions are analyzed by means of the automodelity principle. These functions are considered in the framework of the "light front" formalism for many-body systems. A hypothesis is put forward on the scale invariance of structure functions with respect to the xi-variable, which is some complicated dimensionless combination of kinematic invariants. A simple relation of this variable to the momenta of the nucleons inside the initial nucleus is pointed out. (Atomindex citation 10:493186)

The relativistic quantum mechanics of a complex field has been developed in the framework of which in an explicit form in the expressions for charge Q and momentum P/sup j/ of the field there are considered the terms taking into account the relativity of simultaneity and depending on current density and four-momentum density, respectively. The expressions for Q and P/sup i/, obtained in the momentum space, coincide with the conventional ones. The relativistic position operator x exp 1 is introduced that has the same form as for a non-relativistic approximation. The relativistic analogues of the Ehrenfest theorems are derived. The relativistic invariant definition is given for a three-dimensional delta-function. (Atomindex citation 11:506400)

The problem of massive particle capture by scalar quantum field is studied with the help of the Bogolyubov collective coordinate method. The methods of the system effective mass determination are considered. It is shown that the determination method of the mass, based on the explicit consideration of the system energy dependence on the total momentum, is equivalent to the traditional method which maintains the system velocity determination. That the effective mass consists of two parts - the inert mass of the particle and the "adjoint" mass, associated with the polarization near the particle. Results are illustrated with the help of the Hamiltonian model. (Atomindex citation 11:506411)

Hadron structure is described in the framework in which a nucleon is treated as a composite system of three valence quark clusters, called valons. Their momentum distribution is extracted from deep inelastic scattering data. The valon representation provides a quantitative description of the recombination function, which characterizes the hadronization of quarks. A formalism is then developed in terms of valons and quarks such that the inclusive distributions for hadronic reactions at low-p/sub T/ can be calculated without free parameters. 1 figure. Polarization transfer experiments are now feasible for inelastic scattering experiments on complex nuclei. Experiments thus far have dealt with the spin-flip probability; this observable is sensitive to the action of spin-spin and tensor forces in inelastic scattering. Spin-flip probabilities at E approx. 40 MeV in isoscalar transitions in exp 12 C(12.71 MeV) and exp 15 O(8.89 MeV) show considerable deviation from DWBA-shell model predictions; this deviation indicates evidence for more complex reaction mechanisms. Experiments at intermediate energies will soon be possible and will yield data of much higher precision than is possible at lower (E < 100 MeV) energies. The requirement of a calculable n-p mass difference leads to a consideration of unified gauge theories. Future developments in grand unified models may provide a realistic framework for the calculation of the n-p mass difference. The possibility that the relatively soft ultraviolet behavior of QCD softens the divergence in the lowest-order electromagnetic mass shift is considered in detail. It is shown that, if the bare mass and QCD coupling are constrained to be independent of the electromagnetic coupling, as is natural, then the lowest-order electromagnetic shifts of the renormalized mass and QCD coupling are infinite. The requirement of using self-consistent amplitudes to evaluate microscopically the scattering of strongly interacting particles from nuclei is developed. Application of the idea to a simple model of pion-nucleus scattering is made. Numerical results indicate that the expansion of the optical potential converges when evaluated in terms of fully self-consistent quantities. A comparison of the results to a recent determination of the spreading interaction in the phenomenological isobarhole model shows that the theory accounts for the sign and magnitude of the real and imaginary part of the spreading interaction with no adjusted parameters. The self-consistnt theory has a strong density dependence, and the consequences of this for pion-nucleus scattering are discussed. 18 figures, 1 table. (ERA citation 05:034354)

Data of several series of antiproton-proton annihilation events produced at 1.1 to 2.04 GeV/c are analyzed. The meson resonances with three-body decay (KantiK pi) and particularly the F sub 1 meson, of which quantum numbers spin and parity were not yet determined, were studied. In the antiproton-proton reaction, it was possible to demonstrate the existence of the F sub 1 meson. To test the spin, this experiment used the following processes: the 'angular correlation' tests using the production of F sub 1 associated with the omega as well as the sequential decays F sub 1 implies K*K, K* implies K pi ; the 'positivity' tests, which are directly connected with positivity conditions of the F sub 1 polarization density operator and use only the decay F sub 1 implies K*K. The coherence in the measures obtained in several independent tests allowed one to conclude with good experimental evidence that the spin-parity hypothesis J/sub F sub 1 //sup P/ = 2 exp - is the most probable. The spectrum of prompt neutrons from the exp 252 Cf spontaneous fission has been measured by the time-of-flight method within the wide energy range of 0.01-10 MeV using detectors based on exp 235 U. The results of studies are analyzed and weight average of spectrum within the energy range from 0.01 to 12 MeV is calculated. On the basis of the data obtained the spectrum excess over the Maxwell distribution is shown to be equal to approximately 20% within the energy range of 0.05-0.15 MeV and to 5-7% within the energy range of 0.15-0.4 MeV. Transverse Properties of Hadrons Produced in Neutrino-Nucleon Scattering in BEBC,
B. Saitta. 1981, 21p 87/81

The dependence o ı W of the transverse momentum of hadrons produced ı neutrino-nucleon charged current interactions is stuaied in detail. It is found that in the available W range, the growth of the average transverse momentum squared is not mainly in a plane but the in and out components increase with W at about the same fractional rate. Analyses of energy flow and angular distributions in planar events do not show convincing evidence for high energy, wide angle gluon radiation.

A Computer Analysis of the Plasma-Boundary Layer Behavior over a Positive Electrode.
Master's thesis,
Stephen Ted Van Brocklin. Jun 81, 160p

A stable numerical procedure for solving the coupled, nonlinear equations of electron and ion conservation and electrical potential (Poisson's equation), is described. A two-dimensional model with periodic active sites on a flat plate is utilized to obtain both qualitative and quantitative results which clearly illustrate the self-generating sheath and ambipolar regions adjacent to a non-emitting electrode. The active sites are characterized as voltage sources and by electron densities depressed from both the non-active wall and the free-stream values. Various cases of species density at the nonactive wall are evaluated. Recombination/ionization plays an important role in establishing the boundary layer behavior in the ambipolar region and in the dimensionality of the problem formulation. Application is for Nitrogen gas at one amagat in pulsed discharge of about 50 micro-seconds in duration. Results clearly demonstrate the boundary layer nature of the species density at the electrode. A sheath length of 38 microns about a 35-volt active site and 5-20 microns along the non-active portion of the electrode is established. Joule heating is determined to be not important. (Author)

A brief summary is given of the physics of the problem of laser-mater interaction. In the limit of very low intensities, the absorption is dominated by inverse bremsstrahlung. At higher intensities and in a homogeneous medium, there are several parametric processes that may become significant. The threshold intensities for the onset of several parametric instabilities are listed. Results for threshold intensities and growth rates just above threshold are briefly discussed for an inhomogeneous plasma. A brief description of resonance absorption in an inhomogeneous plasma is included. (Atomindex citation 11:519353)

The computer method application for reconstructing neutron differential energy spectra and calculating the flux from a point (laser plasma) and expanded (THETA-pinch) sources according to the measurement results of the energy spectrum and recoil proton density in nuclear photoemulsions has been developed. The method with the help of which the effect of neutron flying angle scattering on measurement of their spectrum for the point source is described. It is shown that the determination of neutron spectra with the energy of about 3 MeV is possible with the resolution not less than 0.25 MeV. While measuring the expanded source spectrum its form permits to judge the nature and average energy of the neutrons. The method is used for measuring neutron fluxes and energy spectra at the experiments on heating of deuterium plasma. (Atomindex citation 10:492768)

Presented at the 5TH Intern. Conf. On Infrared and Millimeter Waves, Wuerzburg, West Germany, 6-10 Oct. 1980.

A procedure for the maximum entropy spectral estimation is studied for the purpose of data processing in Fourier transform spectroscopy. The autoregressive model fitting is examined under a least squares criterion based on the Yule-Walker equations. An AIC-like criterion is suggested for selecting the model order. The principal advantage of the new procedure lies in the enhanced frequency resolution particularly for small values of the maximum optical path-difference of the interferogram. The usefulness of the procedure is ascertained by some numerical simulations and further by experiments with respect to a highly coherent submillimeter wave and the electron cyclotron emission from a stellarator plasma.

An Energy Integral and Variational Principle for Plasma Kinetic Modes.
S. I. Itoh, K. Itoh, and Y. Terashima. Aug 81, 15p IPPJ-531

An energy principle is extended to include kinetic processes, finite gyroradius effects and wave-particle interactions, in electromagnetic instabilities in a toroidal plasma. The present arguments are based on the energy integrals which are derived from the eigenmode equations for electromagnetic perturbations. Inclusion of the finite gyroradius effects in the energy integral shows that this integral can be used for eigenmode by minimizing the excess energy of the pertubed state. The extended stability conditions for kink-like mode and ballooning mode are obtained by use of this improved energy principle. For the case where wave-particle interaction is important, the energy integral becomes a rate equation of energy exchange, and a variational form can independently be constructed for the mode analysis.

The group structure of chiral representations of OSp(1.4) is studied in detail. The formalism of differential geometry in the physical 4+4-dimensional superspace (SS) is developed on the basis of the simplest supergravity group of general transformations of the coordinates of the left and right chiral SS. In this formalism the only independent dynamical variable is the axial gravitational superfield (SF). All the geometrical objects - supertetrades, affinities, etc. - are expressed in terms of the axial gravitational SF. Analysis of the transformation properties of the spinor-coordinate derivatives has led to a natural definition of the local Lorentz group for SF. The simplest Lagrangian for pure supergravity is discussed. (Atomindex citation 11:506364)

The variational method has been employed to investigate the dynamical stability of solitons of the complex scalar field with the self interaction Jsub(mu)Jsup(mu). The classes of probe functions are proposed which conserve the charge of solitary scalar field lumps. The analytical consideration is completed by results of numerical solution by means of computer of nonstationary nonlinear partial differential equation. The spherically symmetric solitons in this model turn out to be unstable for all alpha omega alpha < 1 unlike the one-dimensional ones, which are apparently stable for all alpha omega alpha < 1. The eigenvalue problem has been formulated to find the instability growth rate in the linear approximation in this model. (Atomindex citation 10:492395)

Upper Limits for the Number of Bound States Associated with the Yukawa Potential,
Herbert S. Bennett. 23 Jul 80, 6p
Included in Jnl. of Research of the National Bureau of Standards, v86 n5 p503-508, Sep-Oct 81.

The number of bound-state solutions of the Schrodinger equation for the screened Coulomb potential (Yukawa potential), --(C/r) exp(-alpha r), occurs frequently in theoretical discussions concerning, for example, gas discharges, nuclear physics, and semiconductor physics. The number of bound states is a function of (C/alpha). Three upper limits for the number of bound states associated with the Yukawa potential are evaluated and compared. These three limits are those given by Bargmann, Schwinger, and Lieb. In addition, the Sobolev inequality states that whenever (C/alpha) less than 1.65 no bound state occurs. This agrees to within a few percent of the numerical calculations of Bonch-Bruevich and Glasko. The Bargmann and Lieb limits and the Sobolev inequality are substantially easier to evaluate than the Schwinger limit. Among the three limits, the Schwinger limit gives the most restrictive limit for the existence of only one bound state and, therefore, is the best one to use for the approach to no binding, i.e., 1.65 less than (C/alpha) less than or equal to 1.98. The Lieb limit is the best among the three when (C/alpha) is greater than 1.98. The Bargmann limit is the least restrictive.

The objective of the present study is to derive a dynamic crack curving criterion applicable to both mode I and combined modes I and II crack tip deformation. To this goal, dynamic extension of two static crack curving criteria, that is the maximum circumferential stress criterion and the minimum strain energy density criterion at a critical distance rc, was considered. The developed theoretical relations were evaluated numerically and crack velocity on crack curving direction were deduced. Crack curving angles predicted by the two dynamic crack curing criteria were then compared with experimental results, obtained from past dynamic photoelastic investigation.

An Improved Transverse Shear Deformation Theory for Laminated Antisotropic Plates.
M. V. V. Murthy. Nov 81, 39p NASA-TP-1903, L-14533

An improved transverse shear deformation theory for laminated anisotropic plates under bending is presented. The theory eliminates the need for an arbitrarily chosen shear correction factor. For a general laminate with coupled bending and stretching, the constitutive equations connecting resultants with average displacements and rotations are derived. Simplified forms of these relations are also obtained for the special case of a symmetric laminate with uncoupled bending. The governing equation for this special case is obtained as a sixth-order equation for the normal displacement requiring prescription of the three physically natural bounday conditions along each edge. For the limiting case of isotropy, the present theory reduces to an improved version of Mindlin's theory. Numerical results are obtained from the present theory for an example of a laminated plate under cylindrical bending. Comparison with results from exact three-dimensional analysis shows that the present theory is more accurate than other theories of equivalent order.

In some respects the proposed modal test proram resembles earlier sine-sweep and sine-dwell testing in that broadband FRF's are acquired using several input locations, and tuning is employed to refine the modal parameter estimates. The major tasks performed in the proposed modal test program are outlined. Data acquisition and FFT processing, curve fitting, and modal tuning phases are described and examples are given to illustrate and evaluate them.

Collapse Analysis of Three Dimensional Assemblages of Eccentrically Stiffened Hot Rolled Steel Plates and Shallow Shells,
R. S. Puthli. 1980, 49p
Pub. in HERON, v25 n2 1980.

This paper describes a finite element formulation of the large-deflection, elasto-plastic behavior of eccentrically stiffened steel plated assemblages in more than one plane. The theory is based on a lagrangian formulation for moderately large deflections, using rectangular plate elements and stiffener line elements that may be given initial deformations and slopes to form shallow shells. Plasticity in the plate is treated using Ilyushin's yield criterion, whereas a simple uniaxial yield criterion is adopted for the stiffeners. Torsional stiffness of the stiffeners is treated in a linear-elastic manner and torsional instability (stiffener tripping) is not considered. A computer program (CASPA) has been developed for the analysis. Classical, numerical and experimental examples are compared with numerical solutions obtained from computer analyses. The numerical solutions commence with geometric imperfections at zero load, with an incremental approach up to collapse.

The major emphasis has been on an experimental study of impact ionization in Pt/nGaAs and Pt/pInP <100> Schottky barrier and developing the theoretical background necessary to interpret the measurements. The intention here was to establish the Schottky barrier as a configuration which would permit more reliable measurements of impact ionization coefficients than p-n junction configurations. (Author)

The magnetic susceptibility of microgram quantities of exp 248 CmP and exp 248 CmSb has been determined with the use of a SQUID micromagnetic susceptometer over the temperature range 4.2 to 340 K and in the applied magnetic field range of 0.45 to 1600 G. The fcc (NaCl-type) samples yield magnetic transitions at 73K and 162 K for the phosphide and antimonide, respectively. Together with published magnetic data for CmN and CmAs, these results indicate spatially extended exchange interactions between the relatively localized 5f electrons of the metallic actinide atoms. ESCADT: A FORTRAN Code for Computing the Positions and Areas of X-Ray Photoelectron Spectral Peaks.
L. E. Cox. Sep 79, 22p
Contract W-7405-ENG-36

Program ESCADT uses least-squares-derived convoluting numbers to smooth and differentiate x-ray photoelectron spectra. Peak maxima are located by finding zero crossings of the first derivative and refined using a cubic polynomial fitting procedure. Background points are located using the product of the absolute value of the first derivative and the smoothed ordinate value. Peak areas, using both linear and scattered electron backgrounds, are computed. Spectra are corrected for changes in instrument sensitivity and energy calibration with gold-standard data retrieved from a disk file. Five determinations of the gold 4f peak positions yielded standard deviations of 0.011 and 0.031 eV for the 4f/sub 7/2/ and 4f/sub 5/2/ peaks, respectively. The relative standard deviation for the computed areas was 0.85%. (ERA citation 05:003417)

Contract W-7405-ENG-36

The fifteenth quarterly progress report of the Los Alamos Scientific Laboratory program to develop Nb sub 3 Ge as a superconductor with potential applications to power transmission lines covers the period January 1-March 31, 1980. During this quarter, additional instrumentation was installed on the first 1-m Nb sub 3 Ge cable in preparation for tests, which are now scheduled for May 1980. Three Nb sub 3 (Ge/sub 1-x/Ga/sub x/)pseudobinary compounds were prepared with compositions approaching the proper stoichiometry and with x = 0.08, 0.12, and 0.15, respectively. The replacement of germanium by gallium causes a slight depression (approx. 1.0 K) of T/sub c/ and does not appear to influence H/sub c sub 2 / significantly. A microscopic examination of the edge material on sections of our Nb sub 3 Ge-clad tape revealed longitudinal cracks extending along the edges of tapes with Nb sub 3 Ge thickness t greater than or equal to 4.0 mu m. Tapes with t = 3.0 mu m show no evidence of such cracks, corroborating conclusions reached by ac loss measurements. The two layers of the inner conductor of the first 1-m test cable were wound with tapes coated with 4 to 6 mu m of Nb sub 3 Ge and are expected to contain longitudinal cracks. The two layers of the outer conductor of this coaxial cable were fabricated from tapes coated with approx. 3.0 mu m of Nb sub 3 Ge and should exhibit lower ac losses. (ERA citation 05:034379)

Computer simulation results for the dynamic-structure factors of a ferromagnetically-coupled, classical one-dimensional easy-plane spin system are compared with calculations based on a linear spin-wave theory, for the case where a magnetic field is applied in the easy plane. The case of zero-applied field is also considered, and here the results are compared with the low-temperature theory of Cieplak and Sjolander.

Detailed theoretical and experimental studies of the dopant density, hole density, hole mobility, and resistivity in p-type silicon were carried out over a wide range of dopant density (10 to the 14th power to 3 x 10 to the 18th power/cc) and temperature (100 to 400K). Good agreement between theory and experiment was obtained, and the theoretical models appear to be adequate for interpreting the temperature and dopant density dependence of resistivity of boron-, gallium-, and indium-doped silicon over the ranges studied.

This paper determines the density weight factors needed to evaluate the Helmholtz free energy for the Ising model of the lattice gas through tenth order in the coupling constants for arbitrary density and interactions. This is accomplished by developing new generating functions for the evaluation of the density factors that are associated with the articulated vertices which result from summing over the 'hard-core' part of the interaction potential. Application to the nearest neighbor model reproduces known results for the simple cubic (s.c.) and body-centered cubic (b.c.c.) lattices,

and extends the known face-centered cubic (f.c.c.) results by two orders.

Computation methods for tropospheric propagation losses in transhorizon propagation are used to provide estimates for the detectability of over-the-horizon targets. Losses depend on frequency, distance, climate, refractivity, and on an empirically derived attenuation function which also takes into account the effects of antenna heights. Equivalent antenna temperatures are assumed to be due to galactic noise. Receiver noise is characterized by noise figure F. Signal-to-noise ratios are illustrated for several target cross-sections as a function of frequency and distance, parametric in antenna heights, distance or frequency, for the median loss 50%, as well as 1, 10, 90, and 99% levels of variability. The residuals between observed oblique sounder medium maximum observed frequencies (MOF) and predicted maximum usable frequencies (MUF) were used to assess the accuracy of high frequency MUF prediction. 4668 MOF's measured on 25 paths were compared against the predicted values from ITSA-1, HFMUFES 4 and MINIMUF-3.5. The data was screened into subsets to see the effect of particular paths, path length and orientation, season, month, latitude, sunspot number, diurnal trends, geographic region and sounder type. MINIMUF-3.5 was most accurate, having a bias of 0.08 MHz (0.6 percent) and a root mean square (rms) error of 3.71 MHz (3.6 percent). It was least accurate during the sunrise and sunset transition hours and for path lengths 5000 to 7000 km. Linear regression analysis identified the probable source of this error to be in the M factor calculation. Except for land paths the performance of HFMUFES 4 was disappointing. It was least accurate for paths over the ocean and with lengths between 4000 and 5000 km. Linear regression analysis identified the source of this error to be a bias in the foF2 numerical coefficient map over ocean areas. The 'k sec Phi'. factor accentuated this bias as the range increased. The version of ITSA-1 with ionospheric characteristics mapped in universal time appeared to be slightly more accurate than the one with its characteristics mapped in local time. All of the programs had difficulty predicting MUFs accurately at high latitude. (Author)

This report is a short survey intended to present the effect of solid and melting hydrometeors on millimeter radio waves. Hail and sleet were found to be more amenable to theoretical calculation and laboratory experimentation than snow because of their simpler approximations of particle shape and dielectric constant. However, field measurements on hail and sleet are scarce in comparison to snow. The most pressing need was found to be the gathering of reliable field data on the morphology and size distribution of hydrometeor particles, particularly those in a melting state where the effect on millimeter waves may exceed that of rain. These data are needed to more closely relate experimental measurement to theoretical calculation. (Author)

A computer program is developed for calculations the transmission characteristics of a rectangular aperture in a perfectly conducting plane excited by an incident plane wave. The solution is obtained from the integral equation for the equivalent magnetic current using the method of moments. The expansion functions and testing functions are pulses in the direction transverse to current flow, and triangles in the direction of current flow. Quantities computed are the equivalent magnetic current and the transmission cross section patterns. To illustrate the solution, computations are given for narrow slots and for square apertures. The computer program is described and listed with sample input-output data. (Author)

Contract NAS5-25993

The problem of correcting the antenna temperatures observed with a single reflector is addressed from two viewpoints with emphasis on decreasing the level of the side lobes without greatly amplifying the noise. One viewpoint is that of matrix operations where the elements of the matrix are integrals of the antenna pattern. This formulation is directly applicable to developing algorithms. The other is that of an analysis of the problem by treating the antenna as a spatial filter and using Fourier transforms of the antenna pattern. This approach leads to an understanding of the problem, but is not suitable for performing calculations. The method developed can be used to correct data from mechanically-scanned microwave instruments that view Earth from space.

This technical report describes the results of a 12-month program to design, build, and test a fiber optic viewing device (fiberscope) on a high pressure gas turbine combustor rig. High speed motion picture photography along with video tapings were made of the combustor flame with the fiberscope. With the high speed photography the turbulent flame motion could be followed in some detail. Visible wavelength spectra were taken of the flame emission through the fiberscope and analysis indicates that a mean flame temperature can be measured. The fluctuation frequency spectrum of the flame was also observed with a fast fourier transform analyzer, and the possibility of coupling with acoustic resonances was indicated. In addition, the fuel spray was illuminated with laser light from the fiberscope probe and contour plots were made of a sequence of frames from the movie film. The combustor viewing probe may be used as an important aid in future combustion design and to help determine causes of various failure modes of combustor liners. (Author)

An Investigation of Flame Stability in a Coaxial Dump Combustor.
Doctoral thesis,
Edward T. Curran. 18 May 79, 243p AFIT/AE/DS79-1, AFIT-CI-79-215D

An experimental investigation of the flame stability characteristics of a coaxial dump combustion chamber was made. A 6-in. diameter combustor was studied, and the dump plane inlet diameter was varied from 2.5 in. to 5.0 inches Tests were carried out using premixed ethylene/air and JP-4/air. To avoid vitiation effects, a clean-air heater was used to vary the temperature of the inlet air. The temperature levels were generally in the range 1000-1250 R; the corresponding inlet pressure was varied between approximately 10 and 40 psia. Inlet Mach numbers were typically in the range 0.2 to 0.9. The flame stability data were not collapsed by a conventional dump combustor correlation. However, a correlating parameter was derived by modelling the annular recirculation zone as an adiabatic stirred reactor using a one-step chemical reaction. This derived correlating parameter was used to obtain successful correlations. Some tests were performed with additional fuel injection directly into the recirculation zone. Lean extinction limits were determined with varying fractions of the total fuel flow being injected into the recirculation zone. These tests yielded an estimate of the air mass flow fraction entrained into the recirculation zone. Finally, tests were performed using a transparent quartz combustor; it was observed that the combustion process was an oscillatory phenomenon with the reaction zone moving rapidly to and fro along the combustor. A comprehensive review of the literature concerning the flame stability and aerodynamics of coaxial dump combustors was presented.

Slag vaporization is a serious problem in high-temperature coal combustion and gasification processes. As the combustion or gasification gases cool on passage through process equipment, the slag will recondense, often with very deleterious effects. For example, in gasification processes even small concentration of slag vapors can result in poisoning of catalysts and fouling

of heat exchanger tubes. The ultimate goal of this research program is to create an apparatus capable of studying the nucleation of the products found in high temperature coal gasification and combustion. Since real coal combustion is a very complicated process with many reaction species, an experimental design was chosen which will allow successively more complicated reactant streams to be used, yet which at every stage are quite realistic approximation to real processes. A multiported flat flame burner, was constructed for the study. Preliminary nucleation studies are described. (ERA citation 06:034275)

Fundamental data on ignition delay, volatile burn time, volatile reactivity, char burn time, char reactivity, aerodynamic drag, particle surface temperature, and internal porosity of burning coal particles are being obtained as a function of coal type, particle size, gas temperature, gas velocity and oxygen concentration. Simulation of conditions inside a furnace has been achieved in two tests rigs which have been constructed. In the first rig single coal particles 3 to 12 mm in diameter are suspended on a 0.02 mm diameter stainless steel wire which extends from an electronic balance into a 50 mm dia. tube containing flowing electrically heated gas. This setup extends the traditional thermogravimetric analysis to flowing systems. In the second rig coal particles are levitated freely in a 50 mm diam, diverging insulated quartz nozzle. To date 16 fixed particle test runs have been made-7 with a Kentucky bituminous coal, 3 with a Montana sub-bituminous and 6 with a Texas lignite. Gas temperatures ranged from 760 to 1140 exp 0 K, flow rates from 2 to 11 scfm, gas-particle velocities from 1.8 to 10.4 m/s, and Reynolds Numbers from 100 to 1150. The reactivity of the coal particles during devolatilization and char burn was calculated from the slope of the mass versus time curve and using the initial external surface areas. For the levitated particle tests the reactivity can be calculated from the CO sub 2 and CO curves. The results of the reactivity calculations to date are summarized. The reactivity data will be used to develop a theory of coal combustion which includes mass transfer and kinetic effects. (ERA citation 06:034271)

This program is concerned with the provision of a technology base to expedite the conversion of industrial processes from oil and gas to coal and other pulverized fuels. It addresses primarily the impact of fuel type on the thermal performance of a combustor. The program incorporates two experimental tasks and is constructed around an analytical task (Task 1) which will identify and upgrade a family of computer programs required to undertake thermal performance analysis studies. These analytical tools will thus be used to predict the effects of parameters such as fuel type and furnace variables on combustor performance, and to identify those properties which have a major impact on thermal performance. The second task uses a combustion reactor to screen the key variable identified in Task I and to provide data on the properties of coal particulate matter which affect heat transfer performance. Verification of the engineering analytical approach will be provided by measurements made in a pilot-scale furnace in the third task. Progress is reported. (ERA citation 06:035358)

An experimental program directed toward demonstrating efficient catalytic combustion of fuel-lean mixtures of residual fuel and air, and assessing the influence of incomplete fuel vaporization on the performance of a catalytic reactor has been conducted. A fuel injection system was designed to provide uniform catalytic reactor inlet properties and a controllable level of fuel vaporization. The reactor was a graded-cell device constructed from Corning MCB-12, zirconia-spinel substrate. The elements were catalyzed with a UOP noble metal, proprietary catalyst. The fuel preparation and catalytic reactor components were used in tests with No. 6 oil, No. 2 oil or blends of residual fuel (No. 6 oil or shale residual oil) and No. 2 oil. The several tests performed with No. 6 oil indicated that complete vaporization of the fuel would be required to achieve satisfactory catalytic operation. Tests were performed with blends of either No. 6 and No. 2 oil, or a shale residual oil and No. 2 in an attempt to determine a threshold level of the heavy constituent for satisfactory combustor operation. The results suggested that no level of No. 6 oil was conducive to satisfactory performance unless complete vaporization was achieved. Shale oil blends were identified which resulted in stable operation without bursts of luminous particles exiting the reactor. This fuel differed from the No. 6 oil by having a lower temperature final distillation point; that is, it did not contain the high molecular weight species contained in the No. 6 oil. Tests performed with the shale oil blends indicated that the combustor performance was sensitive to the degree of fuel vaporization. A similar effect was observed in tests performed with No. 2 oil. An experimental program was conducted to evaluate the process feasibility of the first stage of the HITS two-stage coal combustion system. Tests were run in a small (12-in. ID) fluidized bed facility at the Energy Engineering Laboratory, Aerojet Energy Conversion Company, Sacramento, California. The first stage reactor was run with low (0.70%) and high (4.06%) sulfur coals with ash fusion temperatures of 2450 exp 0 and 2220 exp 0 F, respectively. Limestone was used to scavenge the sulfur. The produced low-Btu gas was burned in a combustor. Bed temperature and inlet gas percent oxygen were varied in the course of testing. Key results are summarized as follows: the process was stable and readily controllable, and generated a free-flowing char product using coals with low (2220 exp 0 F) and high (2450 exp 0 F) ash fusion temperatures at bed temperatures of at least 1700 exp 0 and 1800 exp 0 F, respectively; the gaseous product was found to have a total heating value of about 120 Btu/SCF at 1350 exp 0 F, and the practicality of cleaning the hot product gas and delivering it to the combustor was demonstrated; sulfur capture efficiencies above 80% were demonstrated for both low and high sulfur coals with a calcium/sulfur mole ratio of approximately two; gasification rates of about 5,000 SCF/ft exp 2 -hr were obtained for coal input rates ranging from 40 to 135 lbm/hr, as required to maintain the desired bed temperatures; and the gaseous product yielded combustion temperatures in excess of 3000 exp 0 F when burned with preheated (900 exp 0 F) air. The above test results support the promise of the HITS system to provide a practical means of converting high sulfur coal to a clean gas for industrial applications. Sulfur capture, gas heating value, and gas production rate are all in the range required for an effective system. Planning is underway for additional testing of the system in the 12-in. fluid bed facility, including demonstration of the second stage char burnup reactor. (ERA citation 06:035356)

Lewis Research Center's Coal-Fired, Pressurized, Fluidized-Bed Reactor Test Facility.
J. A. Kobak, and R. J. Rollbuhler. Oct 81, 35p NASA-TM-81616, E-621

A 200-kilowatt-thermal, pressurized, fluidized-bed (PFB) reactor, research test facility was designed, constructed, and operated as part of a NASA-funded project to assess and evaluate the effect of PFB hot-gas effluent on aircraft turbine engine materials that might have applications in stationary-power-plant turbogenerators. Some of the techniques and components developed for this PFB system are described. One of the more important items was the development of a two-in-one, gas-solids separator that removed 95+ percent of the solids in 1600 F to 1900 F gases. Another was a coal and sorbent feed and mixing system for injecting the fuel into the pressurized combustor. Also important were the controls and data-acquisition systems that enabled one person to operate the entire facility. The solid, liquid, and gas sub-systems all had problems that were solved over the 2-year operating time of the facility, which culminated in a 400-hour, hot-gas, turbine test.

Cocurrent Three-Phase Fluidized Bed. Part 2.
G. M. Burck, K. Kodama, R. G. Markeloff, and S. R. Wilson. 19 May 75, 66p
Contract W-7405-ENG-26

Operating characteristics and gas-liquid mass transfer have been examined in a cocurrent three-phase fluidized bed using an air-carbon dioxide gas mixture, water, and three packings. Minimum fluidization velocities were determined, but correlation of the volume fraction of each phase with packing characteristics was only successful for the solids due to scatter in the data. Several improvements are suggested. The concentration profile for 4 x 8 mesh alumina beads approximated a plug flow model, and the K/sub L/a was about twice that for 0.25-in. Plexiglas spheres whose profile approached a CSTR model. The K/sub L/a and the degree of dispersion for a bubble column at similar flow conditions were between values found for the columns containing alumina and Plexiglas packings. Unresolved Issues Resulting from Changes in DOE's Synthetic Fuels Commercialization Programs.
17 Aug 81, 14p Rept no. GAO/EMD-81-128
See also Rept. no. GAO/EMD-81-36.

On June 30, 1980, with the passage of the Energy Security Act, the Congress authorized a substantial financial and planning assistance program designed to spur development of alternatives to imported oil. As part of this effort, the Congress intended to accelerate the development of synthetic fuels in the United States. In an effort to achieve a 'fast start' the act authorized an interim program, which is being implemented using existing Federal departments, particularly DOE, while awaiting the establishment of the Synthetic Fuels Corporation (SFC). The interim program at DOE was funded at over $5.5 billion. This funding is broken down as follows: $3 billion for incentives to develop synthetic fuels for defense needs (Defense Production Act). Incentives would be in the form of loan guarantees, purchase commitments, and price guarantees; $2 billion for incentives to produce synthetic fuels from oil shale, tar sands, coal-oil mixtures, coal, and hydrogen production by electrolysis (Federal Nonnuclear Energy Research and Development Act). Incentives were available in the form of loan guarantees, purchase commitments, and price guarantees; and $.5 billion for synthetic fuel feasibility studies and cooperative agreements. Feasibility study grants are intended to accelerate assessment of the technical and economic feasibility of proposed commercial synthetic fuel plants by funding such efforts as preliminary designs and environmental monitoring and analysis.

Synthetic Fuels Corporation's Management of Demonstration Projects Would Be Limited.
10 Jul 81, 33p Rept no. GAO/EMD-81-116

Department of Energy management and technical direction of fossil fuel demonstration projects differ substantially from that contemplated by Synthetic Fuels Corporation officials. Under requirements of the Energy Security Act of 1980, the Synthetic Fuels Corporation cannot have any direct role in the construction or operation of a demonstration project. Although the Corporation can participate in management decisions, primary management responsibility must be given to the private sponsor of the project. While DOE would use over 100 staff members for monitoring and direction, the Corporation may only have one full-time employee devoted to the project relying more heavily on the sponsor's management and control system. Fractionation of Diesel Fuel from Petroleum and Paraho Shale Oils.
Final rept.,
Charles F. Hammer. Oct 81, 22p DTNSRDC/SME-80/212
Contract N00167-76-M-8549

A fractionation scheme has been developed to separate diesel fuels into neutral water solubles, acidic components, basic components, saturated hydrocarbons, substituted benzenes, polycyclic aromatic hydrocarbons, and polar neutrals. A sample of conventional petroleum diesel fuel and a sample of diesel fuel derived from Paraho crude shale oil by the Gary-Western process were fractionated by this procedure. Each fraction was further analyzed by gas chromatography and proton magnetic resonance spectroscopy. The petroleum sample was found to contain 17.5% total aromatics of which 9.5% were polycyclic aromatic hydrocarbons compounds. However, the Paraho-Gray Western shale oil fuel contained about twice as much total aromatics (38.2%) and polycyclic aromatic hydrocarbons compounds (19.3%). The total acyclic hydrocarbon straight chain compounds content was 66.7% for the petroleum sample and 59,3% for the Paraho-Gary Western shale sample. Suggestions for further work are also made. Research into the effects of alcohol on engine lubrication and wear has investigated four alcohol-containing fuels; pure methanol, pure ethanol, methanol in unleaded gasoline, and ethanol, in unleaded gasoline. This research work has indicated that during low-temperature engine operations such as winter commuter service and warmup, use of pure methanol may result in increased engine wear. This increased wear appears to be primarily a low-temperature problem. With the engine warmed to normal operating temperatures, this increased wear has not been observed. To this point, the research with ethanol-containing fuels has not detected any wear increases. This may be due to the short duration engine tests being conducted, but nevertheless indicates that increased wear should be of less concern with this fuel. Wear mechanism studies have indicated that corrosive attack within the piston ring and cylinder area by alcohol combustion byproducts is partially responsible for the increased wear. Investigation of alcohol and lubricant compatibility and physical removal of the lubricant films by liquid alcohol have provided additional insights into these wear phenomena. (Author)

The United States Synthetic Fuels Corporation's Project Selection Guidelines Need Clarification.
5 Aug 81, 5p Rept no. GAO/EMD-81-129

The SFC's (Synthetic Fuel Corporation) project selection guidelines provide information on the process for evaluating proposals, the criteria to be used, and their relationship to the requirements of the Energy Security Act. It appears that the guidelines are consistent with the requirements of the Energy Security Act. However, in reviewing the public comments, we found that probably the principal criticism is that they are vague. There is concern that industry sponsors may not have enough guidance to adequately prepare their proposals. Also, the Environmental Protection Agency and environmental groups would like the environmental groups would like the environmental criteria to be clearer and more complete. Our comments similarly concern areas in need of clarification. We found that the SFC needs to clarify the project selection process by describing in greater detail how projects will be reviewed and by establishing a target date for beginning the review of 'mature' projects. The SFC also needs to clarify how economic assumptions, such as inflation rates, interest rates, and the price of oil and gas, will be standardized so that the financial viability of a project can be assessed and compared with other projects. Furthermore, to ensure the integrity of the project selection process, the SFC needs to maintain detailed documentation at each level of the process.

This is the second in a series of monthly reports requested by certain members of the Senate Committee on Energy and Natural Resources and the House Committee on Interstate and Foreign Commerce on the administration's activities to implement title VIII of the Energy Security Act. This second report discusses the administration's activities taken between September 5, 1980, and October 17, 1980, to fill the SPR. Enclosure I presents additional details on the results of the August 1980 competitive exchange of SPR oil, deliveries made to the SPR, the readiness of SPR facilities to accept oil, and the administration's efforts to increase the SPR fill rate beyond 100,000 barrels per day. This report is based on interviews with officials in DOE, the Defense Fuel Supply Center, and the Office of Management and Budget, and on publications, studies, and DOE and Defense Fuel Supply Center program documents related to SPR.

This is the sixth in a series of status reports requested by members of the Senate Committee on Energy and Natural Resources and the House Committee on Energy and Commerce on the administration's activities to implement title VIII of the Energy Security Act. (See enc. II for the July 23, 1980, letter requesting these reviews.) Title VIII requires the President to resume filling the Strategic Petroleum Reserve (SPR) at an average rate of at least 100,000 barrels per day for fiscal year 1981 and succeeding years. Our most recent report on the status of SPR fill activities (EMD-81-85, May 4, 1981) noted that, since passage of the Energy Security Act, the Government had issued contracts for about 75 million barrels of oil to be delivered to the SPR during fiscal year 1981. This is equivalent to an average fill rate of about 205,000 barrels per day for the entire fiscal year. However, on April 24, 1981, the Department of Energy (DOE) postponed purchases of additional oil for the SPR for about 30 days because it hoped to take advantage of expected decreases in crude oil prices during the period.

Design, Construction, and Operation of a Full Scale Experimental Anaerobic Fermentation Facility. Final Report.
Jun 81, 235p DOE/ET/20009-T1
Contract AC01-77ET20009

Under DOE Contract No. EG-77-C-4015, the Hamilton Standard Division of United Technologies Corporation has designed, constructed and operated a 25 ton per day anaerobic fermentation facility to evaluate the technical and economic viability of producing fuel gas and an animal refeed product from the residues of an environmental beef cattle feedlot. The system was built at a feedlot owned by Kaplan Industries Inc. (KII) in Bartow, Florida. KII contributed the site for system construction, the cattle to provide manure as system feedstock, certain capital equipment and the labor, utilities and supplies for the system operation. Florida Power Corporation contributed a 440 kW grid-connected engine/generator system. After operating conditions were reached during the summer of 1979, the system has been in continuous operation and has been producing between 3 to 5 cubic feet of methane per pound of volatile solids fed to the system. Product gas has been successfully utilized in: the system process boiler which maintains thermophilic operating tem-

perature in the fermentors; a meat packing plant process boiler, cofired with fuel oil; and a 440 kW grid-connected engine/generator system. Although the feeding trials that will establish the value of the dewatered effluent have been performed, the final results are not yet available. Initial operation of the system indicates that it will be a technically and economically viable process. (ERA citation 06:034517)

Experimental Work Related to Two Bismuth Sulfate Cycles and Their Possible Improvement. Outline of a Possible Antimonyl Sulfate Cycle with Separate Evolution of Sulfur Dioxide and Oxygen.

Contract W-7405-ENG-36
International Energy Agency Annex I workshop on thermochemical hydrogen, Julich, F.R. Germany, 23 Sep 1981.

Two bismuth sulfate cycles are made possible by the stepwise decomposition of the sulfate-oxysulfate system. Omitting statement of the steps for decomposition of SO sub 3 and the electrochemical formation of H sub 2 and H sub 2 SO sub 4 from SO sub 2 and H sub 2 O, the key reactions are: Cycle I - Bi sub 2 (SO sub 4) sub 3 = Bi sub 2 O sub 2 sub 3 (SO sub 4) sub 0 sub 7 + 2.3 SO sub 3 ; Bi sub 2 O sub 2 sub 3 (SO sub 4) sub 0 sub 7 + 2.3 H sub 2 SO sub 4 = Bi sub 2 (SO sub 4) sub 3 + 2.3 H sub 2 O; Cycle II - Bi sub 2 O(SO sub 4) sub 2 = Bi sub 2 O sub 2 sub 3 (SO sub 4) sub 0 sub 7 + 1.3 SO sub 3 ; Bi sub 2 O sub 2 sub 3 (SO sub 4) sub 0 sub 7 + 1.3 H sub 2 SO sub 4 = Bi sub 2 O(SO sub 4) sub 2 + 1.3 H sub 2 O. Cycle I proceeds through the intermediate oxysulfates Bi sub 2 O(SO sub 4) sub 2 and Bi sub 2 O sub 2 SO sub 4 and Cycle II through Bi sub 2 O sub 2 SO sub 4 . Cycle I has the advantage of generating 2.3 moles of H sub 2 per mole of Bi sub 2 O sub 3 , compared with 1.3 for Cycle II. Published work on the Bi sub 2 O sub 3 -SO sub 3 -H sub 2 O system shows that Bi sub 2 (SO sub 4) sub 3 is the stable solid in contact with H sub 2 SO sub 4 solutions above 52.7 wt%, so that acid of at least this strength would have to be used in Cycle I. Concentrations between about 3 wt% and 52.7 wt% could be used for Cycle II. The efficiency for electrochemical formation of H sub 2 SO sub 4 and H sub 2 seems at present to be a maximum at around 30 wt% H sub 2 SO sub 4 . Some thermodynamic data obtained for the decomposition reactions are presented. A possible improvement in these cycles is also discussed which may provide a solution to a problem of sorption of H sub 2 SO sub 4 solution by the solids and might allow use of a more dilute acid than in Cycle I above. A brief discussion on the possible simplification of the SO sub 3 -SO sub 2 -O sub 2 separation problem with a sulfuric acid-antimonyl sulfate hybrid cycle is presented. The principal reactions are: (1) Sb sub 2 O sub 2 SO sub 4 = Sb sub 2 O sub 4 + SO sub 2 at 900 K; (2) Sb sub 2 O sub 4 = Sb sub 2 O sub 3 + 1/2 O sub 2 at 1300 K; (3) Sb sub 2 O sub 3 + H sub 2 SO sub 4 = Sb sub 2 O sub 2 SO sub 4 + H sub 2 O. Contract FG22-80PC30249

A three-parameter corresponding states framework developed originally for light hydrocarbons has been modified to rapidly develop a practical thermodynamic properties prediction capability for the coal conversion industry. The three-parameter corresponding states correlation is shown to accurately describe the thermodynamic behavior of pure non-polar and slightly polar non-associating coal fluids and mixtures for which the mixture constituents are known. Characterization techniques are outlined for converting distillation analysis of undefined mixtures (with composition available in terms of broad fractions) into representative pseudo-components. Empirical correlations have been developed to estimate the three correlations have been developed to esitmate the three corresponding states characterization parameters for each fraction from measurements made on the fraction (boiling point, specific gravity, molecular weight). Extension of the three-parameter corresponding states framework to a multiparameter framework to predict the thermodynamic behavior of polar and associating pure coal fluids is presently being persued. Interim results for one and two ring polar and associating coal fluids indicate that an extension of the corresponding states methodology to associating fluids using a five-parameter correlation is possible. Progress reports are presented for the following two areas: catalytic cracking studies with water-wet silica-alumina catalysts; and Fischer-Tropsch reactor studies where similarities and differences between fixed bed and slurry type reactors are investigated and further experiments conducted to measure mass transfer coefficients and reaction kinetics which are to be used in a model slurry reactor. The following are some of the conclusions. (1) The premise that the presence of liquid water might increase catalytic cracking activity was found to be invalid. It was demonstrated that cracking can occur at previously unobserved low temperatures (though at low conversions) and that an anomaly exists in that one of the catalysts tested shows an entirely different cracking behavior and probably follows a different cracking mechanism. (2) the diameter of a fixed-bed Fischer-Tropsch reactor critically affected the resistance of the reactor to plugging caused by the build up of carbonaceous or waxy deposits. Plugging was very likely due to local nonuniformity in the catalyst temperature. Decreasing the reactor diameter at a fixed gas space velocity, should improve temperature uniformity by decreasing the length of the thermal conduction path and increasing the extent of convective heat transfer from each catalyst particle. Suppression of plugging at higher H sub 2 /CO ratios is likely due to a reduction in the product average molecular weight and the reaction with hydrogen of carbon deposited via the Boudouard reaction. A slurry bed reactor with its much greater isothermicity can be expected to behave similarly to very small diameter fixed bed reactors and therefore have a higher tolerance of lower H sub 2 /CO ratio feed gas. A literature review reveals that Fusarium strains decompose cellulose, hemicelluloses, and lignin, as well as ferment five- and six-carbon sugars to ethanol. During the first part of Phase II (first half of FY 1981) in this program, research efforts focused mainly on continuing the: (a) isolating, culturing, and maintaining of Fusarium strains for biochemical evaluation; (b) screening for potentially cellulolytic F. strains; (c) searching for lignolytic and hemicellulolytic F. strains; (d) screening for effective pentose- and hexose-fermenting F. strains; and (e) evaluating various methods and materials for the optimization of certain fermentation parameters. Approximately 200 additional Fusarium isolates were isolated and screened; all showed cellulolytic activity, with 50 showing increased activity. Several isolates that formed fusoid to spheroid spores and cells on xylan media were observed to retain their morphology in cellulose suspensions. All tested isolates were found to ferment glucose to ethanol; some yielded amounts of ethanol approaching those produced by yeast. In screening more than 600 isolates for xylose fermentation, 25 were identified as effective fermenters. Reutilization of inoculum during consecutive fermentations was employed to facilitate higher ethanol yields from xylose. A few Fusarium isolates indicated relatively high ethanol tolerability. Behavior of Alkali Metal-Acid Phosphates During Elevated Temperature Water Electrolysis.
M. Steinbugler. 19 Aug 81, 14p UCID-19192
Contract W-7405-ENG-48

We are exploring the use of molten salts containing water as electrolytes for the high temperature (approx. 300 to 400 exp 0 C) electrolysis of water as part of a research program on Thermochemical Cycles for the Production of Hydrogen. The purpose of this study is to determine the behavior of the phosphate-based electrolytes KH sub 5 (PO sub 4) sub 2 , LiH sub 5 (PO sub 4) sub 2 , and NaH sub 5 (PO sub 4) sub 2 , during electrolysis. We are most interested in their characteristics as a function of temperature, the degree of dehydration, and effects of neutralizing cations. We observed the behavior of these molten salts while measuring the cell potential as a function of time at constant current densities up to 1 A/cm exp 2 using platinum electrodes. We also monitored the cell resistance before and after polarization in order to correlate the electrolyte conductivity to the degree of dehydration. Our experiments demonstrated several important characteristics of the electrolytes. Perhaps the most obvious characteristic is the tendency to dehydrate in an open container. This loss of water increases the potential for any given current and temperature for each electrolyte. It does so primarily be increasing the resistance of the electrolyte. This dehydration effect was most pronounced in the sodium- and lithium-based electrolytes, with the potassium-based electrolytes showing a relatively slow dehydration rate. However, the resistances for the sodium-based electrolytes were generally lower than for the potassium-based electrolytes when the water content was high. The lowest cell potentials were obtained for the sodium-based electrolyte at 300 and 350 exp 0 C. However, any conclusions based on our cell potential measurements are of limited value at this time due to the qualitative nature of our experiments especially in regard to the uncertainties in water contents of the melts. The model is accessed as part of the MASEC Models Library, a general purpose modeling framework. It consists of two phases: engineering analysis and economic analysis. User inputs are stored in a data base and may be retained for future use. Model outputs include a recap of user inputs, calculations for gas production, digester heat requirements, system revenues, yearly cash flow, and a graph of the net present value of the investment. The model is generalized so that non-farm applications may also be analyzed. The economic assessment can be prepared for individuals, corporations, and non-profit organizations. The program will work equally well for various digester designs such as continuously stirred reactors, plug-flow systems, and fluidized-bed columns. A preliminary listing of residential No. 2 heating oil and coal prices for cities included in the SOLCOST Data Bank is presented. The list shows the name of one company chosen at random in each city. Rates of companies in the same city are relatively the same, therefore, only one company is represented. The name is shown so as not to misrepresent any other companies. The information shown represents the data as quoted by each company. This includes the basic rate, the taxes, and the delivery charge, if not included. The minimum represents the minimum amount sold to any one customer. Computations have been made to show cost per gallon of fuel oil, cost per ton of coal, cost for both commodities with taxes, and cost-per-million Btu. Taxes are calculated on the basic rate and does not add the delivery charge where it is not included. The Btu values used in converting to cost-per-million Btu are 136,000 Btu per gallon of fuel oil number two and 25,070 Btu for coal. These values will vary from city to city. Conversion of Municipal Solid Waste to Energy, Jacksonville, Florida, Phase I Report.
Jul 81, 237p DOE/CS/20231-1
Contract AC01-79CS0231

The concept feasibility study reported herein was sponsored by the US Department of Energy's (DOE) Urban Waste and Municipal Systems Branch. It is an objective of this Branch to assist in the development of new technology and tc foster the commercialization of innovative concepts for energy recovery from municipal solid waste (MSW). Thus the DOE sponsored a program to evaluate and implement the Scientific Energy Engineering (SEE) auger combustion system. The system is a two chamber, starved-air incinerator so named because of the auger located within the primary chamber which tumbles and moves the waste through the system. A 250 tons per day (TPD) prototype facility located in Jacksonville, Florida, was tested and evaluated. The test report is included in its entirety as an attachment to this study. The commercial version of the system, with a capacity of 350 TPD, was developed by Boeing Engineering and Construction Company (BEC) which is licensed to design and market the system for SEE. The evaluation of applying resource recovery in the City of Jacksonville, Florida, involved the determination of the following: (1) the amount and characteristics of the solid waste; (2) the location and requirement of candidate energy customers and materials markets; (3) the applicable incineration/heat recovery and resource recovery technologies; and (4) the institutional, legal, and environmental requirements for constructing a facility. An implementation plan was developed to define the specific steps required to employ a waste-to-energy technology in the Jacksonville area. (ERA citation 06:034482)

Design, Engineering and Evaluation of Refractory Liners for Slagging Gasifiers. Sixth Quarterly Technical Progress Report, No. M6043-6(QTPR).

Contract AC05-78OR13410

Considerable research is required to establish optimum refractory system and design methods for slagging coal gasifiers. This program is a first attempt at the required research. While there have been a number of programs to test refractories for slagging gasifiers, there have been none which have tested more than a few small specimens of each refractory or closely simulated gasifier conditions. On this program, approximately 40 cu ft (over 600 9 in straight equivalents) of refractory will be tested during each run in the environment of a typical slagging gasifier. By testing this large amount of refractory, material variations are averaged out and a closer approximation to liners for large gasifiers is achieved. In addition, cooling system performance can be studied. (ERA citation 05:026782)

The work described here was accomplished during the period October 1, 1979-September 30, 1980. Highlights of the experimental program were: a solids decomposition facility was constructed and used to study the handling of bismuth oxysulfates and the kinetics of their decomposition; and the results of our kiln experiments showed that a substantial amount of bismuth oxysulfate decomposition occurs with residence times under 2 min. at temperatures between 973 and 1143 exp 0 K. The LASL bismuth sulfate sub-cycle thus appears a candidate for hydrogen production utilizing a solar heat source. In the evaluation phase of our work, the technoeconomics of the hybrid sulfur cycle were determined and compared with several published results as well as compared to the technoeconomics for water electrolysis processes for hydrogen production. We aided the efforts of the Department of Energy (DOE) Thermochemical Cycle Evaluation Panel in reviewing the Lawrence Livermore Laboratory (LLL) zinc selenide cycle as well as the General Atomic (GA) sulfur-iodine cycle. Underground coal conversion symposium, Afton, OK, USA, 13 Jul 1980.

An underground coal gasification (UCG) field test in bituminous coal was successfully completed near Princetown, West Virginia. This test was performed by US DOE's Morgantown Energy Technology Center with Mound Facility providing the major instrumental and field crew support. The primary objective of this field test was to determine the viability of the Linked Vertical Well (LVW) technology to recover the 900 foot (275 m) deep, 6 foot (2 m) thick coal seam. A methane rich product gas with an average heating value greater than 200 BTU/SCF (7452 KJ/m exp 3) was produced at low air injection flow rates during the initial phase of the test. This high methane content has been attributed to the nature of the bituminous coal which has a very high volatile matter content. The methane formation can be accounted for by thermal and hydrocracking of tars and oils along with hydropyrolysis and hydrogasification of coal char. The high heating value of the gas was the combined effect of residence time, flow pattern, injection flow rate, injection pressure and backpressure. Thermocouple data have been used to speculate on the path development and the effects of conduction and convection model on the test system. During the gasification phase, a gas with an average heating value of approximately 124 Btu/SCF (4620 KJ/m exp 3) was produced which resulted in an average estimated energy production of 510.9MM Btu/day. The recovery of hydrogen from such metal hydrides as LiH, MgH2, TiH2, CaH2 and FeTiH compounds is studied, with the aim of evaluating the viability of the technique for the storage of hydrogen fuel. The pressure-temperature dependence of the reactions, enthalpies of formation, the kinetics of the hydrogen absorption and desorption, and the mechanical and chemical stability of the metal hydrides are taken into account in the evaluation. Economic aspects are considered. Development of portable metal hydride hydrogen storage reservoirs is also mentioned.

Contract NAS3-21977

Scale model fuel heating systems for use with aviation hydrocarbon fuel at low temperatures were investigated. The effectiveness of the heating systems in providing flowability and pumpability at extreme low temperature when some freezing of the fuel would otherwise occur is evaluated. The test tank simulated a section of an outer wing tank, and was chilled on the upper and lower surfaces. Turbine engine lubricating oil was heated, and recirculating fuel transferred the heat. Fuels included: a commercial Jet A; an intermediate freeze point distillate; a higher freeze point distillate blended according to Experimental Referee Broadened Specification guidelines; and a higher freeze point paraffinic distillate used in a preceding investigation. Each fuel was chilled to selected temperature to evaluate unpumpable solid formation (holdup). Tests simulating extreme cold weather flight, without heating, provided baseline fuel holdup data. Heating and recirculating fuel increased bulk temperature significantly; it had a relativley small effect on temperature near the bottom of the tank. Methods which increased penetration of heated fuel into the lower boundary layer improved the capability for reducing holdup.

The possibility of using LaNi56, FeTiH2, or MgH2 as metal hydride storage sytems for hydrogen fueled automobile engines is discussed. Magnesium copper and magnesium nickel hydrides studies indicate that they provide more stable storage systems than pure magnesium hydrides. Several test engines employing hydrogen fuel have been developed: a single cylinder motor originally designed for use with air gasoline mixture; a four-cylinder engine modified to run on an air hydrogen mixture; and a gas turbine.

Prepared in cooperation with Environmental Protection Agency, Washington, DC., New Jersey Dept. of Environmental Protection, Trenton, City of Camden, and Camden County Municipal Utilities Authority.

The interaction between microbial heat output (at the expense of the waste being treated) and temperature was identified as the fundamental factor in controlling the composting process. The concept was implemented by means of a temperature feedback control system in conjunction with forced pressure ventilation. Field trials involved raw sewage sludge mixed with woodchips, on a scale of up to 20-ton piles. The new process, which is presently available technology, is called the 'Rutgers static pile composting process'. Some of its advantages are as follows: A starting moisture content of 75 percent is decreased to 25 percent in 12 days; This tendency to dry represents the decomposition of putrescible (odor-causing) organic matter; No condensate is produced; The need for a curing stage can be assessed in terms of specific, objective criteria; The process is operationally flexible to meet the vagaries of environmental regulation; The drying tendency might be exploited in the preparation of biomass-derived fuel.

Research and development work was undertaken to find novel hybrid electrochemical cycles for the production of hydrogen from water and to examine relevant electrolytic reactions in aqueous solution for generating hydrogen; reactions were to be restricted to inorganic compounds and metal deposition was to be avoided. Investigations dealt with the selection of electrolytes and complementary thermochemical reactions and with the identification of reactions critical to the thermochemical cycles and their substitution by electrolytic reactions. Three hybrid processes were investigated involving copper, iron, and antimony. It was concluded that electrolytes generating only hydrogen were of interest for hybrid cycles. Reduction to gaseous hydrogen should be combined with the oxidation of metallic cations in an acid medium. Electrolytic oxygen generation must be prevented.

Tests on the utilization of low-grade fuels were carried out on Toarcian bituminous shales and the coal shales of the Northern Pas-de-Calais Basin in a pyrolysis shaft furnace, a rotating furnace, a coal dust furnace and an Ignifluid furnace. Under technical conditions, the combustion of Toarcian bituminous shales requires enrichment with either coal or gas. Even the indirect combustion process (with a pyrolysis shaft furnace) is far from satisfying economic requirements. However, they might be reached with higher grade bituminous shales. The technical feasibility of using coal shales, especially in pulverized form, has been established. However, the additional charges incurred by an industrial plant at the preparatory stage of the fuel as well as by complying with environmental standards must be taken into account. Nevertheless, it may be possible to ensure satisfactory economic conditions if the coal shales are used in blends. Economically, whatever route is chosen, the utilization of these low-grade fuels is handicapped because of the size of the industrial plants required, which entails high capital expenditure with risks that are difficult to assess and made worse by equipment maintenance problems.

An Analytical and Experimental Analysis of Factors Affecting Exhaust System Performance in Sea Level Static Jet Engine Test Facilities.

David Laurence Bailey. Dec 72, 130p

The study was motivated by a request from the Naval Air Rework Facility, NAS North Island, that work be conducted to obtain information on parameters affecting exhaust system performance in sea level static jet engine test facilities. The cost of pollution abatement devices makes it mandatory that accurate knowledge of flow parameters be developed. The study investigated by theory and experiment certain parameters of test cell design. A computer program based on the one-dimensional mass, momentum and energy conservation equations was developed. Components were designed to test on a scale of 24:1 the effects of varying exhaust system configurations. Theoretical results were found to be in good agreement with experimental data, indicating that the program may be used to analyze full scale systems. Recommendations for

future development in the analysis and experimental program were made. (Author)

Design and Fabrication of Coanda Suppressor Flow Visualization Model,
Dale W. Brees. 10 Feb 77, 37p Rept no. D3-11158-1

Because the Navy Coanda noise suppressor exhibited three-dimensional flow anomalies a 1/20th scale transparent laboratory model was fabricated to provide for visualization of the internal flow. Identification of flow anomalies and methods of correcting them by geometric design changes thus eliminating local acoustic lining erosion was the primary purpose for the model. In addition, model experimental flow data were to be correlated to analytical computer codings so they could be applied to Coanda suppression system designs with a higher level of confidence.. The 1/20th scale transparent model was fabricated and installed in the Boeing-Wichita air laboratory. Several checkout runs were made and the functional capability of the system was verified. These checkout runs showed that the model accurately represents the full scale flow and recirculation that had been deduced from the full scale demonstration tests. (Author)

Performance of an Oswatisch Inlet with Hemispherical Centerbody at Zero Angle of Attack.
Master's thesis,
John Francis Moran. Jun 81, 87p Rept no. NPS67-81-009
ARPA Order-4035

This thesis analyzes the performance of a ramjet with an Oswatisch inlet using a blunt centerbody and compares performance to a baseline ramjet using an inlet with a conical spike at Mach 3.0. Inlet performance as a ratio of inlet tip to nose centerbody ratio, r sub L/r sub n, is developed. The capture streamline for each ratio is determined and the coefficient of additive drag is calculated as a function of r sub L/r sub n. Setting thrust coefficient equal to coefficient of drag, the performance of two ramjets is determined. One ramjet is the baseline with a spike inlet; the other ramjet uses the blunt centerbody. Ramjets and inlets are compared on the basis of specific fuel consumption, excess thrust coefficient and specific thrust. For the ramjet with blunt centerbody, performance parameters were calculated as a function of inlet lip radius to nose centerbody radius. Also compared is the effect of the ratio, r sub L/r sub n, on relative detection range. For both types of ramjets, the detection range is reduced by approximately 66%. Performance of the ramjet with blunt nosed centerbody is severly handicapped due to high additive drag and poor pressure recovery. Specific fuel consumption is approximately 50% greater for the ramjet with the blunt centerbody compared to the ramjet with the spike inlet. (Author)

Multistage Axial Compressor Program on Tip Clearance Effects.
Contractor rept. May 79-Aug 81,
I. Moyle. Aug 81, 49p NPS-67-81-01CR
Contract N62271-80-M-2504

Tip clearance has long been known to be a source of losses in axial compressors with cantilevered blades. The reasons for the losses, however, are not well understood and current practice in engine design still requires extensive effort to maintain constant minimal operating clearances over a wide range of conditions. The emphasis on clearance control may be appreciated by the typical observation that a ten percent change in peak static pressure rise in a compressor stage may occur for a fifty percent change in clearance. Clearances are typically in the one to five percent of major passage dimension range, and thus a small change in passage dimensions represents a large change in clearance. It is clear that, in general, it would be desirable that blading performance be less sensitive to changes in clearance. Less sensitivity would allow a general relaxation of the mechanical tolerances on a compressor assembly and provide more consistent transient performance. The aerodynamics of achieving such a situation are a challenge as the underlying requirement is improved performance at larger clearances. Work toward understanding the basic mechanisms of tip clearance effects with an emphasis on designing for clearance has been commenced at the Naval Postgraduate School turbopropulsion Laboratory (NPS/TPL). This report summarizes the preliminary work on the Multistage Compressor (MSC) facility at the Laboratory.

Final Report.
B. Lakshminarayana. Oct 81, 104p NASA-CR-3471, PSU-TURBO-R81-3
Contract NGL-39-009-007

The flow processes in rocket pump inducers are summarized. The experimental investigations were carried out with air as the test medium. The major characteristics features of the rocket pump inducers are low flow coefficient (0.05 to 0.2) large stagger angle (70 deg to 85 deg) and high solidity blades of little or no camber. The investigations are concerned with the effect of viscosity not the effects of cavitation. Flow visualization, conventional and hot wire probe measurement inside and at the exit of the blade passage, were the analytical methods used. The experiment was carried out using four three and two bladed inducers with cambered blades. Both the passage and the exit flow were measured. The basic research and boundary layer investigation was carried out using a helical flat plate (of some dimensions as the inducer blades tested), and flat plate helical inducer (four bladed). Detailed mean and turbulence flow field inside the passage as well as the exit of the rotor were derived from these measurement. The boundary layer, endwall, and other passage data reveal extremely complex nature of the flow, with major effects of viscosity present across the entire passage. Several analyses were carried out to predict the flow field in inducers. These included an approximate analysis, the shear pumping analysis, and a numerical solution of exact viscous equations with approximate modeling for the viscous terms.

Contract NAS3-22129

Transonic flow through a cascade was studied by using the full potential equation and the finite volume method of Jameson and Caughey. The C-type computational grid is generated by an electrostatic analogy and simple shearing transformation. The solution algorithm includes an option of using either an artificial density or an artificial viscosity formulation of the dissipative term. Using the developed code, flows through a cascade of NACA 0012 airfoils and flows through a cascade of shockless blades were computed. It is found that the designed flow through the shockless blade is accurately predicted, the artificial density formulation shows more tolerance to the mesh irregularity, and the C-type mesh does not extend very far upstream for a small pitch-cord ratio.

New Molding Method of Three-Dimensional Hollow Photoelastic Model and Centrifugal Stress Analysis of Air Cooled Turbine Blade Model.

In English; Japanese Summary.

A new molding method for a three dimensional hollow photoelastic model was invented and centrifugal stress analysis performed for air cooled turbine blade models to which the new method was applied. A distinctive feature of the molding method is the introduction of a copper coated wax core which forms a three dimensional hollow shape inside a model. The air cooled turbine photoelastic model with a coolant passage simulates the first stage rotor blade in the high temperature turbine full scale model HT-10H used at the NAL. The results of stress analysis cleared the critical regions and stress magnitude and thus they are of great aid to the successful development of a full scale turbine model.

JT8D High Pressure Compressor Performance Improvement.
Progress Report, Sep. 1978 - Apr. 1981.
W. O. Gaffin. 11 Nov 81, 47p NASA-CR-165531, PWA-5515-162
Contract NAS3-20630

An improved performance high pressure compressor with potential application to all models of the JT8D engine was designed. The concept consisted of a trenched abradable rubstrip which mates with the blade tips for each of the even rotor stages. This feature allows tip clearances to be set so blade tips run at or near the optimum radius relative to the flowpath wall, without the danger of damaging the blades during transients and maneuvers. The improved compressor demonstrated thrust specific fuel consumption and exhaust gas temperature improvements of 1.0 percent and at least 10 C over the takeoff and climb power range at sea level static conditions, compared to a bill-of-material high pressure compressor. Surge margin also improved 4 percentage points over the high power operating range. A thrust specific fuel consumption improvement of 0.7 percent at typical cruise conditions was calculated based on the sea level test results.

Extensive experience gained with gas turbines operating not only with coal as fuel but also with dusty inlet air and with dirty fuels (such as heavy oils and blast furnace gas) as well as petroleum catalytic cracking units was reviewed. All this experience indicates that the particulate content of the hot gases fed to the turbine must be kept to less than approx. 1 ppM to keep turbine bucket erosion to an acceptable level for turbine inlet temperatures of 1500 exp 0 F or more. Dropping the turbine inlet temperature below 1110 exp 0 F makes it possible to obtain turbine bucket lives of around 3 yr with approx. 100 ppM of particulates if a number of compromises are made in the turbine design. A buildup of deposits in the turbine is a serious problem if sulfates or chlorides are present in the gas stream and the turbine inlet temperature is above approx. 1110 exp 0 F. At this temperature level, these materials become soft and sticky and form films on the blades that accumulate deposits of the silicates and oxides present in the ash of a coal-fired combustor. Extensive experience with many types of cyclone separators shows that they can be used to reduce the particulate content to as low as approx. 100 ppM under the best conditions. Granular bed filters have yielded similar performance. Electrostatic precipitators are not effective above approx. 1110 exp 0 F because the dust deposits on insulators become conducting and short out the grids. The only effective way found to reduce the particulate content of blast furnace gas and gas from coal gasification units to the approx. 1 ppM required for a high-temperature gas turbine is to cool the gas and pass it through a two-stage water scrubber or equivalent before burning it. In brief, it appears doubtful that any of the hot-gas clean-up concepts being investigated will yield the low particulate contents required for the satisfactory, economical operation of 1500 to 1600 exp 0 F long-lived gas turbines. Multidimensional numerical simulations of the reactive fluid flow in an internal combustion engine cylinder are useful in helping engine designers obtain insight into the physical mechanisms governing efficiency and pollutant formation. A comprehensive numerical model for internal combustion engine cylinder simulations that has been developed at Los Alamos is described. The model is currently embodied in a two-dimensional (axisymmetric) computer code called CONCHAS-SPRAY. Work is in progress on a three-dimensional code with the same features. Contract NAS3-22149

Conceptual designs and performance of advanced technology lightweight diesel engines, suitable for commuter type aircraft power plants are defined. Two engines are discussed, a 1491 kW (2000 SHP) eight-cylinder engine and a 895 kW (1200 SHP) six-cylinder engine. High performance and related advanced technologies are proposed such as insulated cylinders, very high injection pressures and high compressor and turbine efficiencies. The description of each engine includes concept drawings, a performance analysis, and weight data. Fuel flow data are given for full and partial power up to 7620m altitude. The performance data are also extrapolated over a power range from 671 kW(900SHP) to 1864 kW (2500 SHP). The specific fuel consumption of the 1491 kW (2000 SHP) engine is 182 g/hWh (.299 lb/HPh) at cruise altitude, its weight 620 kg (1365 lb.) and specific weight .415 kg/kW (.683 lb/HP). The specific fuel consumption of the 895 kW (1200 SHP) engine is 187 g/hWh (.308 lb/HPh) at cruise altitude, its weight 465 kg (1025 lb.) and specific weight .520 kg/kW (.854 lb/HP).

Methods of determining the contact surface temperature in reciprocating seals are investigated. Direct infrared measurement of surface temperatures of a rod exiting a loaded cap seal or simulated seal are compared with surface thermocouple measurements. Significant cooling of the surface requires several milliseconds so that exit temperatures may be considered representative of internal contact temperatures.

A computer model of the combustion-gas-side heat transfer was developed to predict the effects of a jet impingement system and the possible range of improvements available. Using low temperature (315 C (600 F)) pretest data in an updated model, a high temperature silicon carbide jet impingement heat transfer system was designed and fabricated. The system model predicted that at the theoretical maximum limit, jet impingement enhanced heat transfer can: (1) reduce the flame temperature by 275 C (500 F); (2) reduce the exhaust temperature by 110 C (200 F); and (3) increase the overall heat into the working fluid by 10%, all for an increase in required pumping power of less than 0.5% of the engine power output. Initial tests on the GPU-3 Stirling engine at NASA-Lewis demonstrated that the jet impingement system increased the engine output power and efficiency by 5% - 8% with no measurable increase in pumping power. The overall heat transfer coefficient was increased by 65% for the maximum power point of the tests.

A prototype sonic, variable-venturi automotive carburetor was evaluated for its effects on vehicle performance, fuel economy, and exhaust emissions. A 350 CID Chevrolet Impala vehicle was tested on a chassis dynamometer over the 1975 Federal Test Procedure, urban driving cycle. The Micro-carburetor was tested and compared with stock and modified-stock engine configurations. Subsequently, the test vehicle's performance characteristics were examined with the stock carburetor and again with the Micro-carburetor in a series of on-road driveability tests. The test engine was then removed from the vehicle and installed on an engine dynamometer. Engine tests were conducted to compare the fuel economy, thermal efficiency, and cylinder-to-cylinder mixture distribution of the Micro-carburetor to that of the stock configuration. Test results show increases in thermal efficiency and improvements in fuel economy at all test conditions. Improve fuel/air mixture preparation is implied from the information presented. Further improvements in fuel economy and exhaust emissions are possible through a detailed recalibration of the Micro-carburetor.

The five major tasks of the program are reported. Task 1 is a literature search followed by selection and definition of seven generic spacecraft classes. Task 2 covers the determination and description of important disturbance effects. Task 3 applies the disturbances to the generic spacecraft and adds maneuver and stationkeeping functions to define total auxiliary propulsion systems requirements for control. The important auxiliary propulsion system characteristics are identified and sensitivities to control functions and large space system characteristics determined. In Task 4, these sensitivities are quantified and the optimum auxiliary propulsion system characteristics determined. Task 5 compares the desired characteristics with those available for both electrical and chemical auxiliary propulsion systems to identify the directions technology advances should take.

A comprehensive theeoretical model for ignition of composite solid propellants was proposed as a framework for formulating ignition models for different propellants under a wide range of operating conditions. Detailed chemical kinetics information for the AP/PBAA propellants was incorporated into the proposed theoretical model for ignition of composite solid propellants, enabling a more complete description of source terms in the gas-phase energy and species equations. Solid-phase energy equations were coded and implemented on a computer. Numerical solutions of the solid-phase subprogram were successfully checked against analytic solutions for some limiting cases. Using actual measured heat flux near the propellant surface as an input to the solid-phase equations, predictions for the ignition delay time were made. Effects of pressurization rate, crack-gap width, and igniter-flame temperature on the ignition of AP-based composite solid propellants located at the tip of an inert crack were studied. The ignition process was observed by using a high-speed camera (-40,000 pictures/s) and a fast-response photodiode system. Heat flux to the propellant surface was measured with a thin film heat-flux gage. A bright luminous zone behind the reflected compression wave was observed at high pressurization rates. The decrease in ignition delay with increasing pressurization is caused by enhanced heat feedback to the propellant surface at higher pressurization rates.

A critical review of the present policy was conducted with emphasis on its application to future planetary exploration. The probable impact of recent data on the implementation of the present policy was also assessed. The existing policy and its implementation were found to: be excessive for certain missions (e.g., Voyager), neglect the contamination hazard posed by the bulk constituent organics of spacecraft, be ambiguous for certain missions (e.g., Pioneer Venus), and treat all extraterrestrial sample return missions alike. The major features of the proposed policy are planet/mission combinations, a qualitative top level statement, and implementation by exception rather than rule. The concept of planet/mission categories permits the imposition of requirements according to both biological interest in the target planet and the relative contamination hazard of the mission type.

The Effects of Lateral Aerodynamic Uncertainties on the Handling Qualities of the Space Shuttle Orbiter at Mach Numbers of 1.5 and .6.
L. W. Brown. Sep 81, 42p NASA-TM-83193

The effects of aerodynamic uncertainties on the handling qualities of the space shuttle orbiter were investigated with the use of six-degree-of-freedom, nonlinear equations of motion on the hybrid computer system. Flight condition characteristics for Mach numbers of 1.5 and .6 for the nominal and off nominal angle of attack conditions were selected for this investigation. Results revealed that at the low Mach number condition (.6), only a few problems existed for the angle of attack range considered and the many combinations of large aerodynamic variations considered. Moreover, none of these problems were considered to be related to poor handling qualities. For the angle of attack conditions considered at the high Mach number (1.5) problems existed with reduction of roll rate which can result in roll reversal conditions. In many cases, sideslip became proverse and increased rudder deflections and yaw jets were required.

Nonparametric Identification of a Class of Nonlinear Close-Coupled Dynamic Systems.
F. E. Udwadia, and C. P. Kuo. 1 Oct 81, 76p NASA-CR-164948, JPL-PUB-81-48

A nonparametric identification technique for the identification of close coupled dynamic systems with arbitrary memoryless nonlinearities is presented. The method utilizes noisy recorded data (acceleration, velocity and displacement) to identify the restoring forces in the system. The masses in the system are assumed to be known (or fairly well estimated from the design drawings). The restoring forces are expanded in a series of orthogonal polnomials and the coefficients of these polynomial expansions are obtained by using least square fit method. A particularly simple and computationally efficient method is proposed for dealing with separable restoring forces. The identified results are found to be relatively insensitive to measurement noise. An analysis of the effects of measurement noise on the quality of the estimates is given. The computations are shown to be relatively quick (when compared say to the Wiener identification method) and the core storage required relatively small, making the method suitable for onboard identification of large space structures.

Presented at the Joint Ifac/Esa Symp. On Automatic Control in Space, Noordwijkerhout, the Netherlands, 5-9 Jul. 1981.

A proposed method for controlling the shape and orientation of very large shallow dish type receiver/reflectors to be used in communication, radiometry and in electronic orbital based mail systems involves connecting a rigid light weight dumbell with heavy tip masses to the shell at its apex by a spring loaded double gimballed joint with dampling. To completely damp the system transient motion in all of the important lower frequency modes, an active control system is required. A mathematical model is extended to include the effects of point actuators located at preselected positions on the shell surface. The formulation of the uncontrolled dynamics assumes an a priori knowledge of the frequencies of all the elastic modes to be incorporated within the system model. As an example, three rigid body modes and six elastic modes are included in the model and six actuators are assumed, none of which lies on a nodal line or circle.

Moire fringe methods for detecting loose space shuttle tiles were investigated with a test panel consisting of a loose tile surrounded by four securely bonded tiles. The test panel was excited from 20 to 150 Hz with in-plane sinusoidal acceleration of 2 g (peak). If the shuttle orbiter can be subjected to periodic excitation of 1 to 2 g (peak) and rigid-body periodic displacements do not mask the change in the Moire pattern due to tile looseness, then the use of projected Moire fringes to detect out-of-plane rockin appears to be the most viable indicator of tile looseness since no modifications to the tiles are required.

A bi-convex foldable elastic tube, suitable for use in self deploying space structures, was subjected to a series of buckling tests to deterine initial buckling loads, collapse loads, and the buckling mode. The tube is cylindrical with a cross-section that is lenticular-like with flared edges. It is capable of being flattened in the center and folded compactly, storing up strain energy in the process. Upon removal of constraint, it springs back to its original straight configuration, releasing the stored strain energy. The tests showed that this type of tube has good resistance to buckling, with the initial buckling loads all falling within or above the range of those for comparable circular cylindrical tubes.

This report summarizes the Maui Optical Tracking and Identification Facility (MOTIF) Transition Program results. A description of the system hardware and software as well as the modifications and system upgrades that were accomplished during the program are presented. The Communications System (CMS) and the Data Transmission System (DTS) tasks represented the major hardware procurements of the MOTIF Transition Program. The CMS has a MODCOMP (MC) II computer system with peripherals and an Analytics TLC-100 Telecommunications Line Controller. A MC IV computer system with peripherals and a Tektronix 4014-1 Graphics Display Terminal comprise the DTS. A MC V system with peripherals constitutes a spare system for both CMS and DTS. The CMS and DTS hardware systems provide the automatic data processing capability and improved communications response time required. They also provide added computer capability for other software enhancements. MOTIF was operated five nights per week, single shift to collect metric, photometric, and LWIR data. Special computer software was developed to process metric and photometric data in support of those operations. On the average and weather permitting, 15 to 30 objects were tracked for metric data with one tasked photometric track per night.

A family of probability densities on this group is examined, and schemes for numerical integration and estimation of satellite attitude are presented with numerical examples. An effort has been made wherever possible to deal with nonlinear problems directly rather than linearizing them. Several questions for further research are raised regarding convolutions of densities on the group, Brownian motion, and the statistics of spin and torque vectors considered as stochastic variables. KEYWORD INDEX

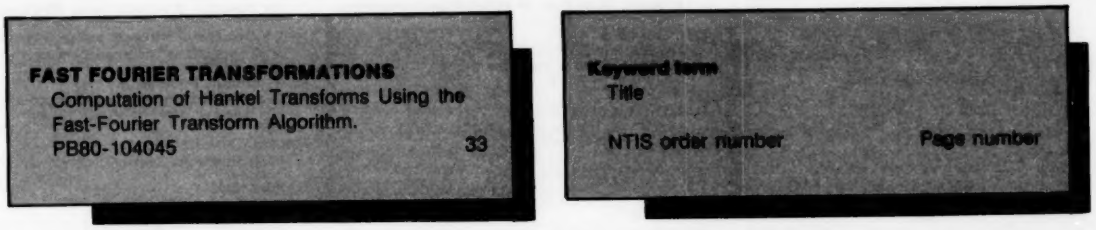
NTIS®

Index entries in this section are selected to indicate important ideas and concepts presented in a report. When using the keyword index, be sure to look under terms narrower, broader, or related to a particular topic. Although some of the keywords are not selected from a controlled vocabulary of terms, most of them have been selected from the DoD, DoE, NASA, or NTIS controlled vocabularies. The entries are arranged by keyword and then by the NTIS order number.

SAMPLE ENTRY



A-7 AIRCRAFT
A Comparison of Theoretical and Experimental Pressure Distributions for Two Advanced Fighter Wings.
N82-11054/5 1078

ABANDONED SITES
Summary of the Engineering Assessment of Inactive Uranium Mill Tailings, Riverton Site, Riverton, Wyoming.
DE82000816 1244

ABATE
TEMEPHOS: O,O'-(thiodi-4,1-phenylene) bis(O,O-dimethyl phosphorothioate), Pesticide Registration Standard.
PB82-140641 1216

ABSORBERS (MATERIALS)
Carbon Dioxide Absorption Characteristics of High Performance Sodasorb at 1 Atmosphere.
AD-A107 488/9 1140

Molecular Sieves. 1976-1981 (Citations from the Energy Data Base).
PB82-858499 1147

Molecular Sieves. 1970-1981 (Citations from the NTIS Data Base).
PB82-858507 1147

ABSORPTION SPECTRA
Symmetry Extinction of LEED Beams for Naphthalene Adsorbed on Pt(III).
AD-A106 963/2 1148

Solitons in Polyacetylene: Effects of Dilute Doping on Optical Absorption Spectra.
AD-A106 964/0 1148

ABSORPTIVITY
A Model Describing the Microwave Emission from a Multi-Layer Snowpack at 37 Ghz.
N82-11510/6 1169

ABSTRACTS
Nasa Patent Abstracts Bibliography: A Continuing Bibliography, Section 1, Abstracts. Supplement 19.
N82-11981/9 1095

ACCELEROMETERS
Trusted Interval in the Fourier Spectra of Accelerograms Digitized Either Manually or by Semi-Automatic Means (Intervalo Confiable en el Espectro de Fourier Obtenido de Acelerogramas Digitizados Manualmente o Con Medios Semiautomaticos),
PB82-135393 1169

ACCESS METHODS
The Subject Access Problem - Opportunities for Solution: A Workshop Held at Springfield, Virginia on 18-20 October, 1978.
PB82-134529 1096

NTIS®

In this index, the name of the company, university, or government agency that performed the research or prepared the report is listed. Entries are arranged first by the organization's name, then alphanumerically by the performing organization report or series number. If no report or series number is included, the subarrangement is by NTIS order number.

NTIS ORDER/REPORT NUMBER INDEX

NTIS®

Entries in this index list the NTIS order number, the performing organization report number, and the sponsoring organization report number, each in its own alphanumeric position. Although reports may be ordered using only the performing organization report number or the sponsoring organization report number, please use the NTIS order number to order items available from NTIS to ensure faster service. It is best to check the full bibliographic citation in the Reports Announcements section before ordering. Entries are arranged alphanumerically.

Foreign NTIS Cooperating Organizations

NTIS is represented in many countries around the world by local organizations. These representatives ensure NTIS clients in those countries of fast and efficient service when transacting business with NTIS. They offer the convenience of accepting payment in local currencies and, any order-related problem can also be resolved by them. These representatives may also serve as an additional channel for non-U.S. information acquisitions.

NTIS clients in the countries listed below should direct all orders and inquiries to these representatives.
